INSANITY AMONG CONVICTS

Read in the Section of Neurology and Medical Jurisprudence, at the Forty fourth Annual Meeting of the American Medical Association

BY M V BALL, M D

PHYSICIAN TO THE STATE PENITENTIARY FOR THE EASTERN DISTRICT OF PENNSYLVANIA

The few cases here presented illustrate some of the types of insanity found among persons convicted f crime

I do not believe the fact of their being convicts influences the insanity in any way, but because of the conditions under which they have been raised, and the selection practiced by courts, the most degenerate classes find their way into prison and thus come to our notice

Very often superficial observers accuse this or that mode of imprisonment as predisposing to insanity As well charge the almshouses with breeding idiots because the mentally defective are found in them

The separate system or cellular plan, as practiced in the penitentiary for the eastern district of Pennsylvania has been accused of driving men insane, and year after year this charge finds its way into print

There are insane prisoners in that institution—some sent there because of their insanity, others whose insanity was not recognized before they were admitted, and some who have become insane during their imprisonment Insanity exists in about the same ratio in other prisons and among the same classes, outside all penal institutions

When we consider the avenues and factors that lead to insanity—syphilis, chronic alcoholism, hereditary defects and the social history of the great mass of prison population, we wonder that insanity is not more frequent among them

Case 1—White male, aged 38, native of Germany Family history negative Childhood uneventful At age of 14 was hit on the head with an iron instrument causing a depression of skull yet visible, and a discharge of pus at the time of the injury Was arrested in Germany for quarreling and while in prison had an attack of probable mania Was arrested in New York city for assault and battery and pronounced insane and sent to an asylum a' Newark, N J His wife obtained his release but he was subsequently returned for abusing her After the death of his wife in 1889, he had intercourse with his 12-year-old daughter, as he claims while under the influence of liquor For this crime he is now serving a sentence of five years He was regarded as insane on admission, and his conduct since has corroborated this opinion He believes himself Christ, God, a poet, writes Bibles, revises them, makes crowns out of paper, talks fluently, though not incoherently Has periods of excitement during which he is homicidally inclined

Case 2—White male, age 44, native of the United States Mother committed suicide and he was reared by strangers Has been arrested six times for larceny, highway robbery and assault and battery, serving in all some eight years in prisons He is now serving his second term here While serving his previous sentence here he attempted suicide by cutting his throat because some of the other prisoners teased him During his present term he has behaved well—has been constantly in separate confinement—answers questions readily and intelligently, has hallucinations of hearing his neighbors speak ill of him and putting spells on him so that at times he can not eat or sleep He believes himself to be an executioner and obliged to "desassinate" people when their time comes He claims that he has put away 3,000 people by striking them on the head or stomach

He expresses his views as follows "To kill a man through malice, that is murder, to kill in self-defense is manslaughter but he is obliged to kill because the court says so" He sleeps well, always turns out his allotted work, says "good day," etc, to his keeper, knows his sentence and when his term expires expects to work on a railroad as brakeman as he has done heretofore

He is intemperate in liquor and venery Eyes staring No other physical signs noticeable

Case 3—White male, aged 23, native of the United States Mother died of phthisis No other family history Has been arrested three times for burglary, serving seven years and is now serving a sentence of five years here On admission giving evidence of symptoms of phthisis, he was placed in an appropriate ward He quarreled with two different cell companions, both of whom he accused of attempting to abuse him He was then placed in separate confinement in another block, this displeased him and he refused to eat, he kept his bed and would not get up, one morning he announced himself as a holy ghost, commanded the keeper to open the cell door and laid on his bed with an ecstatic look and immobile This continued for a few days when he was sent to the hospital where he promised never to call himself the holy ghost Cold baths were given him whenever he disobeyed He ate well, slept well, but at intervals pretended to have religious powers In a few weeks he seemed perfectly normal, and said he would never attempt such actions again He was sent back to the ordinary working cells and in a few days broke out again, singing at night time, etc He was then placed in the coal gang outside where he worked well, and now does miscellaneous work around the corridors apparently well He attempted to run away one day but was caught, and explained that he was afraid he would be hurt When questioned about his previous trouble he says he remembers everything, that he was in the habit of abusing himself, that he is nothing but a man, but something in his way of repeating words and a certain absentness at times, together with very much heightened reflexes make me think that he is not simulating He says that he was always nervous, that he got into crime by running away from home when he was 16 years of age and getting into bad company, and that he can blame no one only himself Once he attempted to hypnotize a fellow convict and when asked about it said, "It is a gift from heaven" He has attempted sodomy At first he believed himself drugged, and poisoned and refused medicines

Case 4—White male, aged 66, native of the United States Family history negative At the age of 8 years had a fracture of the skull which left a depression, but no serious consequences seemed to follow He worked at various occupations from the time of leaving school at 16 until he was 26 years of age Upon one occasion while in a saloon a row occurred and he was shot in the throat and shoulder He recovered after a narrow escape Afterwards he was obliged to change his residence on account of difficulty with an officer At the beginning of the recent civil war he began to raise a company but it was not accepted He tried to enlist but the company was full, but finally succeeded in joining a California regiment, and at the battle of Ball's Bluff was injured in the rectum from the effects of which he was discharged Afterwards he re-enlisted and served until the close of the war hile working on a railroad as a special officer he got a drunken quarrel and shot two men for which crime was sentenced to the penitentiary for five years but was doned at the expiration of five months He subsequently l off a scaffold, broke his nose, crippled his hand and discated one patella After twenty-three years marriage his ife gave birth to her first child and she became insane He hen became intemperate, was placed in an inebriate asylum r a short time and after his release had illegitimate relaions with a woman for four months drinking excessively uring all this period The woman was found one day shot, rom the effects of which she died He was convicted of the crime, was sentenced to a term of twelve years in this institution which is now nearly completed After he had been here six years and was working at carpentering he got an idea he was going to be removed and attempted suicide by twice cutting his throat splitting his head open with a hatchet and cutting a gash across his arm These wounds were all healed and he was returned to the carpenter shop, when he again made a suicidal attempt by driving a spike into his temple When this wound was discovered he said he had fallen on a nail About two years ago he says the devil came into his head again and he tried to cut a vein in his arm He was placed in the hospital where he remains He thinks he hears people talk about him, and worse than all, he hears himself talk about those he likes A voice within him seems to utter curses against his best friends Nowhere was he treated so well and yet this voice will talk, but it is only a delusion as no one ever hears him say anything derogatory He eats and sleeps well, is entirely rational in every way, and I am disposed to believe that his injuries were inflicted with the purpose of exciting sympathy and to prevent his being removed He now works around the yard and is obedient to orders

N B —Removed back to his own cell lately, he has never referred to his hallucinations, a thing he did daily while in hospital

Case 5—White male, aged 36 Father and mother intemperate, and brother a thief He was sent to the house of correction for assault and battery, and claims to have been arrested thirty times for this offense He is now serving a sentence of one year here for larceny in breaking the window of a pawn shop, as he says "to steal" When admitted here he was excited and suffering with acute mania, probably alcoholic in origin His cell was covered with his own filth, his clothes torn to shreds Night and day he kept up constant talk in which prayers and curses were jumbled together He had exaggerated ideas, he was God, he could drink thousands of bottles of beer, he had fifty children etc Hypnotics had little effect on him

This condition continued for several weeks when he was placed at the wheel in the wash house and made to turn the crank, but every now and then he would pick up dirt and eat it or tear his clothes Gradually, however, he became quieter and more tidy, and now he is well behaved but his exaggerated ideas continue, and at times his eyes fill with tears and he promises everything, and then will instantly change and threaten vengeance He says his trouble comes from drink and this appetite he attributes to inheritance from his father His entire illness has lasted about one year

Case 6—White male, aged 39 No satisfactory family history Says his father was hung He has been arrested three times for entering houses Has various insane delusions about electricity, believes he is worth millions, does not associate with the other men in the wash house where he is employed, but whenever the opportunity offers walks off and talks to himself He answers questions only after repeated pressing Recognizes his crime and knows his sentence and expresses the hope that it will be his last Was defective on entrance

Case 7—White male, aged 27 Native of the United States Family and previous personal history good Worked well in prison until five months ago, when his overseer noticed a gradual apathy and disinclination to talk or work A new cell companion had been given him, and to him he would not speak He eats very little and will do no work He lies in bed constantly and when asked what is the matter replies "I do not know" There was slight rise of temperature, cold extremities, and replies to questions in monosyllables and generally "don't know" Physical examination negative Urine normal Tongue coated He gave his name, age, and complained of pain, but does not know where Knee reflexes exaggerated, pupils react normal Was sent to hospital and during the same evening talked with other convicts about shoemaking but only when drawn out

The next day he refused food, said it would not go down Temperature normal No obstruction in throat and so informed him, when he swallowed as usual He remains awake at night murmuring to himself Diagnosis Stuporous insanity, or so called primary dementia Ordered cold baths and abundant light food The latter he now ate readily In a few weeks he seemed sufficiently restored to return to work, in fact, asked to do so Within a few days after returning to work he again relapsed to his former condition, sitting in one place constantly and never speaking Was readmitted to the hospital and put on light work in the yard, but would not move unless constantly urged The fear of the bath was sufficient to impel him to many things His appetite is voracious He sleeps well, answers only after repeated questioning, and then only yes or no Has grown fat, reflexes normal, secretions normal When first admitted to hospital he would allow saliva to gather in his mouth and dribble over his clothes Later he would constantly spit on the floor and soil his bed, but he is now cleanly His head is always bent He never looks at any one Occasionally he can be made to smile He promises to do better when the cold baths or wet cups are suggested There has been but little change in his condition for the past two months Is serving first sentence here for assault and battery

Case 8—Colored male, aged 42 Sister epileptic, he is very ignorant, believes prisoners below him are endeavoring to extract a confession from him and to that end torturing him with electricity He feels electric sparks going through him and hears voices saying, "Turn it on stronger", make him tell us" His suffering from imaginary torture will occasionally be so great at night that he screams out No physical ailment can be detected Moral influences have had some beneficial effect and for weeks he will be apparently well He works regularly A partner was given him, but this seemed to have no effect upon his hallucinations He is serving second sentence for larceny

Case 9—White male, age 40 Nativity, England Family history good Has been convicted four times for larceny, serving in all six years Was similarly troubled in his mind while serving a sentence in Canada While here he believed the food poisoned, spirits came in the walls, he concealed weapons with which he threatened the overseers He was disciplined and has since been quiet and pleasant He claims he has no more delusions or hallucinations He believes he did wrong, and it was proper that he should be punished, but he calls God to aid him, and expresses a wish to die here He sleeps and eats well and is abundantly nourished

Case 10—White male, age 30 Nativity, Austria Family history negative At 9 years of age had a serious illness and was unconscious but does not know what the disease was He is a baker by trade and a sailor by occupation Seven years ago he was convicted of rape on a child 9 years old, and sentenced to this institution for a term of ten years, which is now nearly completed About eighteen months ago he announced he was going to die, it had been revealed to him He stripped off his clothes, refused food, etc This lasted a short time and he became all right again The priest says he had noticed evidences of insanity in him on religious subjects He is one of the best prisoners in the institution He does the work assigned him regularly, believes he is atoning for his crime and no doubt would become easily disturbed if the subject of religion were broached He has only shown this one outbreak, and since has acted rationally and has no other delusions or hallucination

Case 11—Black male, age 20 Family history good Early personal history negative Convicted of breaking in a house When he had been here eleven months developed acute mania, becom[illegible]hy, noisy and destructive Was placed in wash hou[illegible] and now, after two years, has had no recurrence o[illegible] His mind seems well balanced and he has no recollection of the symptoms described above

Case 12—White male, age 32 Family history negative Was addicted to intemperance and venery Convicted of attempting to kill his mistress in a fit of jealousy and sentenced to five years here which he is now serving After the lapse of eighteen months from his admission his cell companion was discharged, and being left alone he began to make a noise and rave *all of which he remembers* He continued in this condition for three months when he was placed in the hospital in association with other prisoners when his raving stopped He desired a partner He accounts for this malady by attributing it to masturbation which he claims to have practiced two or three times nightly As soon as he entered the hospital he appeared all right and has continued so up to this time now three years This was evidently a case of simulation An element in the case was the effort of friends to obtain a pardon for him

Case 13—White male, aged 63 Native of the United States Grandmother and aunt committed suicide He is a machinist by trade and had his skull fractured by an accident, was unconscious at the time and his wife would not permit trephining He showed symptoms of insanity six years ago Has worked sometimes at his trade and sometimes at other occupations Had spells of unconsciousness and forgetfulness He invented a patent and stole tools to complete it and for this was arrested, pronounced insane and sent to an asylum He escaped and wandered around the country working at odd jobs and finally came to Philadelphia where he was caught in stealing some tools and sent here for seven years for attempting to resist arrest by an officer On admission was easily moved to tears, could remember nothing, cried constantly, was worried about his wife and children whom he imagined to be starving, gave an assumed name, seems well educated, has a depression in the skull and begs to be operated upon, either to die or get well Letters from his wife and from the asylum corroborate his statements He has no apparent delusions He left the asylum because he thought he was well and wanted to earn a living for his family His case at times resembles one of cerebral softening

After he quieted down and was given something to do to occupy his mind he became more rational, wrote letters, made a model of his lock out of wood, and eats and sleeps well His memory continues impaired His wife says that when he gets to worrying he has spells of violence, a possible epileptoid condition, and he will leave home and wander around He is yet very easily excited so that he trembles and can not write

Case 14—White male, age 31 Native of the United States Illegitimate child No family history obtainable Mother is very voluble and might be called foolish He is addicted to intemperance and venery He was first convicted of larceny in his twelfth year and has since served six terms for similar offenses Four years ago he was convicted of assault and battery on his wife and sentenced to three years Two days after the expiration of that sentence he was arrested for a similar crime and upon conviction sent here under a sentence of three years, making his eighth conviction and sentence He has hallucinations of hearing People speak about him, and they with his wife are constantly persecuting him He has hallucinations of sight also He is easily excited and angered Eyes staring

Case 15—White male, age 53 Engineer by trade Phthisis on mother's side Had syphilis twenty six years ago, was formerly intemperate in habits He met with an accident during the war in which his skull was fractured This was followed by one month of delirium and one year of dementia Since then there has been no noticeable symptoms except that delirium easily occurs when drunk In a quarrel he struck a friend with his fist and killed him Pupils are pin hole in size, knee jerks greatly exaggerated No other physical symptoms No evidence of any psychical disturbance

Case 16—White male, age 34 Loom fixer by trade Father insane One sister committed suicide while insane He has had "general nervous trouble" for the past four years, with illusions at times Is intemperate in liquor and venery He struck his aged mother a severe blow for ordering him out of the room He has a small head, seems agitated, is very irritable when under the influence of liquor No evidence of any delusions or hallucinations now

Case 17—White male, age 34 Carpenter by trade Father addicted to drink and had a stroke of paralysis, which took him to the almshouse He was convicted of patricide and sentenced to ten years He has tremor of hand knee jerks greatly exaggerated Has been nervous for years When angered he will instantly use any weapon at hand Is bothered greatly by insomnia There is no evidence of delusions or hallucinations

Cases 15, 16 and 17 represent a group that is very interesting and which might be classified as neurotics, not criminal neuropathy as Wood defines a class, but *simple* neuropathy They are persons whose family history shows crime, or insanity, or intemperance, who have always been fidgetty, probably, as children, "bad tempered" when opposed, who *have indulged in liquor to excess*, who have not been dominated by any distinct delusions or hallucinations or impulses, but when opposed in a quarrel they can not control themselves, and the first best thing they can grasp is hurled madly at the object of their sudden passion A moment afterwards they are sorry and curse themselves for their uncontrollable temper

Often we meet children with such ungovernable passions they are feared by their parents and hated by their friends No doubt such moments of anger could be traced in the childhood of many ' homicides of occasion "

The outburst of ill temper found in the early stages of general paralysis is readily diagnosed from that of the neuropathics, because in the former it is unusual and a change from another condition In the latter, however, they have been nervous from childhood

When paralytics commit crimes that are punishable they present so many other phases of their disease that lawyers soon discover it, and they are switched off to the proper asylum

We find among fifty cases showing mental trouble fourteen were indicted for homicide, or 28 per cent, while in the entire penitentiary population only 9 per cent are murder cases (The census statistics of 1890, of all the prisons in the United States gathered by Wines, gives 8 9 per cent of homicides to the total prison population) Eight of our fifty cases were convicted of assault with intent to kill, and seven for rape, making a total of twenty-nine or 38 per cent committed for crimes against persons Of the entire prison population only 30 per cent are sent for crimes against persons while 70 per cent are for crimes against property Thus our statistics support the opinion that insanity leads more often to crimes against persons than against property Very seldom does the crime seem to be the direct outcome of insane delusions

In 40 per cent of our insanities, ideas of persecution, "Verfolgungs Wahn" is clearly developed

The prisoner known as peculiar by his cell companion, tells his overseer some morning that he "should not put any more of that stuff in his food," he sends for the doctor and claims he is being poisoned, he commences to write letters to various persons, the warden, inspectors, etc Again he complains about persons occupying neighboring cells speaking of him, they call him obscene names and accuse him of indecent crimes He abandons work and sits all day in the corner of his cell, speaking only when repeatedly addressed His bowels are or soon become constipated, but otherwise the prisoner appears well His cell and person are kept clean Sometimes he refuses his food for a few days, but is easily persuaded to eat

In some cases religious ideas are intermingled He may believe himself possessed of the holy spirit, God has commanded him not to eat Hallucinations sometimes combine themselves with delusions about his sentence He imagines his time has expired and he is restrained from going out Letters are withheld from him, and a pardon awaits him in the office

Sleep is variable Some rest soundly, while others are kept awake all night by their delusions According to their own explanations, "electrical appliances keep them awake" or "persons come through the windows and awaken them," etc

The hallucinations may each be only of short duration recurring at varying intervals They may be constantly present, but interfering so little with the daily vocation that the prisoner eats, sleeps and performs all tasks without interruption, and his defect is only disclosed by questioning

The hallucinations may disappear entirely and not return during the balance of his term, and only reappear in some form when he returns to serve another term as a re-convict

And just here occurs the difficulty of at once recognizing simulation If one who presents such manifestations of mental disturbance is placed on extra diet, excused from work and receives other privileges given the sick, if he is maligning he will attempt the same deceit whenever he enters a prison And even men who were not simulating the first time may attempt the deceit subsequently on account of the privileges

There are very few forms of insanity in which punishment and reward are not understood

There is at present in this penitentiary a man who is serving a life sentence for murder, committed as a sequence of his insanity, who was always considered "cranky" by the people who knew him He is noisy, filthy and incoherent, yet were I to place him in a hospital cell with others he would be quiet and neat Only at times will he become very talkative This has been tried several times with him with the same result He is not left permanently in the hospital for fear of injury to others

I am acquainted with no possible test to detect all simulation When prisoners will feign to obtain slight favors while in confinement, how much greater is the incentive when on trial for life or liberty

Case 18—White male, age 43 Native of Ireland Family history negative Deprived of father at early age Came to this country with his mother and located in New York city Began to run streets and at 9 years of age was placed in house of refuge At the end of a year in that institution he was bound out on a farm ran away and returned to New York city, where he became a newsboy When 12 years of age he followed a company of soldiers destined for New Orleans and left them at Cairo and began operations as a hotel thief, stealing clothes, etc, and thus working his way back to New York, where he became the associate of a bad crowd At 14 years of age he was sentenced to a year in the New Jersey penitentiary, and three months after the expiration of this term he was returned under a four years' sentence for burglary The night following his release from this term he robbed a guest at a hotel, enlisted in the navy, went by sea to California and there deserted and worked his way East He enlisted in the regular army, fought all through the Modoc war, deserted, went to San Francisco and resumed his occupation of hotel thief He was finally caught and sentenced to four years in the California State Prison While there was witness to the murder of a prisoner by his room mate This brought delusions and he began to imagine people were trying to kill him After his discharge these delusions vanished He resumed his old occupation and worked his way back to New York at the expense of the hotels en route Here he was convicted of another crime and sentenced to Sing Sing for four years In prison his delusions returned and were treated without avail Upon his discharge they again disappeared, and he resumed occupations working the hotels until he reached Chicago, where he was sentenced to four years in the Joliet Penitentiary The delusions returned and continued throughout his confinement Upon his release he worked his way to Philadelphia, and, caught in the act of stealing at the Lafayette Hotel, shot the watchman, and received a sentence of ten years here, which he is now serving He is a quiet man, well behaved here, eats and sleeps well, and rational in all his conversation He does not claim to have been impelled by some uncontrollable force to steal, but did so because that life pleased him

There is another prisoner here who escaped from the Auburn Insane Asylum for convicts, who was sentenced here for breaking into a jewelry store While in the county prison he manifested signs of mania, but here he was rational until one day he had some trouble with his knitting machine, and in his passion wrecked it When reprimanded he said he would do such a thing whenever it bothered him, and threatened any one who attempted to prevent him, that was the way he did in other prisons and that was the way he proposed to do here, he was no one's slave He was disciplined and made to understand that such conduct was not permitted here, and since, there is not a more civil or industrious convict than he in our population There is no evidence of insanity He has spent most of his life in various prisons for burglary Like the previous man noted he follows this occupation as a matter of choice

But, in reality, simulation is rare here More frequently does true insanity go undetected throughout the trial and is only discovered by the prison physician or keeper

That the crimes of the insane bear no relation to their insanity is a well known fact easily established

A man who has hallucinations or delusions of persecution might logically be supposed to commit an assault on the person he imagined as offending, but in fact they are often common thieves and are repeatedly convicted of burglary or larceny As a companion of one such aptly remarked, "he hasn't sand enough to kill a fly"

The crimes against persons are often committed in a drunken quarrel—a man is killed without the slightest premeditation, a rape accomplished or attempted under the influence of liquor, etc

Probably the crimes resulting from insane delusions or hallucinations take their perpetrators to insane asylums, but the record of such crimes is not large

In this connection I am impelled to refer to the usual practice of the courts in the treatment of offenders whether sane or insane—the moral responsibility—"does the man know the right or wrongness of his act," is the usual test

When a person commits an act contrary to the laws of the country a jury is empaneled to decide as to his guilt and all the facts in the case, and when the question is raised, these are made to include the sanity or insanity of the defendant, and what a judge, jury and lawyers take weeks often to decide, an ignorant fellow is asked to do offhand

This question of absolute right or wrong is both a broad and intricate one It involves each man's idea of what is right or wrong and that depends almost wholly upon his education and surrounding influences If this be true is not the man of few social advantages less responsible than those with many? May not an act be right for one individual and wrong for another? Or at least wrong for one and not culpably wrong for the other? And so the worst criminals be less responsible?

How many years is it since we have ceased to punish people for their beliefs?

The common opinion (at least as it finds expression in print) is that justice is not administered in a spirit of vengeance The aim is only to deter, protect and reform If this be the real motive why inquire about the moral responsibility? Is not protection needed as much from the criminal acts of the insane or mentally defective as from the mentally strong?

Beccaria says crimes are only to be measured by the injury done to society, and our modern penologists are approaching the same conclusion Paul Dubuissin (*Archives de l' Anthropologie Criminelle*, Vol vii, No 38), says "When we will only consult the social utility in our treatment of criminals then the great question between crime and responsibility will cease Then will arise in each case not, Is he responsible, but is he dangerous to society? Not, Does he know the difference between good and evil, but is he of more evil than good to society?

It matters not, then, whether we believe with Lombroso that all professional criminals are diseased and therefore irresponsible, or whether the criminal be morally insane, a born criminal, an habitual criminal, an idiot or defective of any class If he is unsocial, society should be as much protected from his acts as she seeks to be against cholera, leprosy or any other corrupting or dangerous or unsafe influence And the more dangerous the more protection

Is the criminal an insane person, or do we find insanity more prevalent among criminals than among honest folks?

The answer to this question depends upon our interpretation of crime and honesty

As we have no real measure for right we can not with entire accuracy say one man is honest and another dishonest Every man on one side of the iron bars is not a criminal, and every man on the other side an honest man Diogenes would have just as much need for his lantern to-day as in the time of Alexander the Great

It is *conviction* that makes a man a criminal in public esteem, not *detection* How many are there among us who have not some time in their lives committed an act that was punishable under the law? and had it been enforced would have sent us to the reformatory or prison, and thus by a simple application of the law, without reference to its violation branding us throughout our future lives as criminals I stole an apple when I was a youngster Many a boy has received a year's sentence for less and obtained his degree in a house of refuge Because I was not caught I am supposed to be honest The other lad is a *criminal*

The smartness of the lawyer keeps many a guilty defendant out of prison The theory is that every man is equal before the law Practically we know this to be a fiction When the machine is in good working order with a batch of poor and friendless victims on hand, they are "railroaded" to prison with so little an attempt at legal defense as to amount to a farce

In view of the self-evident unevenness and partiality in the administration of law, it is impossible to draw the line between the criminal and the non criminal classes so as to compare the diseases peculiar to each

A CASE OF SO CALLED MORAL INSANITY

Case 19—White male, age 23 Nativity, United States One sister reported as having chorea and another puerperal insanity

When eight years old was sent to the house of refuge for running away from home After a residence there for thirteen months he was returned to his home At the expiration of another year he was arrested for larceny and being declared insane was sent to an aslyum and from there to an institution for defective children, and from the latter finally ran away He stole from his parents and was generally so incorrigible that he was placed in the Norristown Asylum as morally insane At the expiration of two years he was discharged and at once returned to his old habits In 1886 was again arrested for stealing from his parents and readmitted to an insane asylum from which he was discharged at the end of a year by direction of the Board of Lunacy In 1890 he was convicted of larceny and sent to the Huntingdon Reformatory, from which institution he was transferred here for incorrigibility He says he is addicted to intemperance, opium, onanism and venery and seems proud of his record His mother can do nothing with him and in the neighborhood of his home he is a common nuisance The first day here he tried to obtain opium through complaining of cramps as he claims to have succeeded in doing in other institutions He failed here, however, and has had no returns of cramps He maligned epileptic fits These were promptly cured by the cold water douche He went through the entire list of troubles to obtain special privileges or escape work, with the regularity of a professional Failing in every attempt and through the assistance of persistent but harmless discipline he has finally been brought into fair submission He has been exhibited as a living example of moral insanity When asked questions before a class of students he would purposely give false and outrageous answers to keep up his reputation His crime history has been obtained and thoroughly established by relatives and acquaintances He is short and fleshy, head brachycephalic, eyes small, teeth irregular, boyish feminine appearance He is very cowardly and fawning—never abusive or angry

Is this lad insane? Is it moral blindness? Was his home training defective? These are questions which no one can satisfactorily answer, and yet society needs to be protected from such a class

He belongs to a class that is rapidly increasing and especially in the large centers of population They are the "incorrigibles" of reformatories and as such are transferred to prisons and inducted into a career of professional criminality which they follow until death The reformatory can not or does not reclaim them, the prison has no terror for them If their energies and genius could be diverted into some useful occupation they might become beneficial members of society

The question whether criminality is due to mental defect, remains unsolved

Mandsley says "The criminal class constitutes a degenerate or morbid variety of mankind marked by peculiar low physical and mental characteristics "

By an artificial selection such as is practiced in our police courts, the man who can afford to obtain able attorneys, or pay fines, or by his talents avoids detection, or by many of the other fortunate or practical known avenues escapes conviction Then as a rule only the poorest, most ignorant and lowest classes are sent to prison, the exceptions being the rare occasion of a great popular clamor where some victim must be taken from the higher class, but these are limited to the very smallest number demanded to satisfy the outcry A prison population so collected must of necessity be degenerate from every point of view

Does insanity appear more frequently in prisons than in communities outside? Authorities in former times have all answered in the affirmative Can this answer be accepted as entirely true? Were these convicts insane before they reached the prison? Did their insanity lead them into crime?

Is it insanity or is it simulation? Semal finds insanity much more prevalent among those outside than those inside prisons. Sir Matthew Hale is quoted as saying "Habitual felons suffer from a degree of partial insanity." This means nothing, as there is no complete insanity. Dr Macdonald of Auburn, in his twenty-third annual report "believes crime to influence the insanities and to constitute them as a distinct class." He remarks on the general absence of expressed delusions, generally coherent in conversations, perform their allotted tasks, display wonderful combinations of shrewdness and cunning in their efforts to escape.

If we compare the lower orders of men in the community at large with those in prison, the proportion of insane in each would not differ much.

The trouble with all our statistics on the subject is that they are one-sided. We must divide society into classes, according to wealth, ability and position, as Chas. Booth has done in his "Life and Labor of the People."

Class "A" in prison must be compared with class "A" outside before any reasonable conclusions are warranted.

We know that insanity does sometimes cause persons to commit crime, but there are many insane who do not commit crime, and there are many criminals who are not insane.

Masoin, at the Anthropological Congress held in Belgium, gave the following differences between the criminal and the insane act: the diseased kill for the sake of the deed—rob for the sake of robbing, without any other aim. The criminal acts out of covetousness or hatred. After the act he seeks to conceal himself; the alien does not.

The crime calms the insane. It troubles the criminal.

When we will recognize that "every society deserves the criminals it has" and we will endeavor to correct the evils that in a large part cause crime, and treat our malefactors not with a spirit of vengeance, not with a visitation of justice, not as sinners but simply as obstructionists, whom society must place under restraint or remove to a place where they can be of service instead of hindrance, then only will the penal question reach a solution.

Has a man stolen my pocket book two years in prison will not return it to me; time can not measure the injury done me or the suffering caused the prisoner. To one man, *ten* days will cause as much anguish as ten years to another.

See how childish our present mode of justice; a man commits 100 burglaries and is caught, he is only charged with two; is sentenced to five years imprisonment. His term is served; he is caught stealing a watch and receives two years. He again returns to burglary, and after awhile is caught and is given another sentence of a few years, and so ad infinitum, ten, eleven sentences, each time a trial, each time efforts to detect him, and the numerous times he wholly escapes detection. What would be thought of the suggestion that a chronic maniac be sent to an insane asylum for one year and then released unconditionally; then after he had killed some one, again returned for a definite term of one or more years?

The danger to society alone should be considered and the professional criminal placed in "durance vile" until *cured*, if that result is possible, or permanently if the danger to society is ineradicable, and this wholly as a protection to society and irrespective of his sanity or insanity, his moral responsibility or irresponsibility, his reformation or punishment.

Chairman.—I think Dr Ball is to be congratulated on doing what has been done too little in this country, namely, working in the prisons for facts in reference to mental diseases, instead of having issued from the officials of prisons and others in authority general statements about matters of this kind. This, I think, is a sort of work which will do for criminology what men have done for other forms of mental disease outside of prisons.

Dr F. P. Norbury of Jacksonville, Ill.—I have met with quite a number of these cases in the Illinois Hospital for the Insane. It is a rule in the Illinois institution, or was until the inauguration of the criminal hospital for the insane, that all criminals found to be insane should be sent to the State Hospital. As a result, we got all cases belonging to the county or district in which the hospital was. I found that quite a number of these cases were not chargeable with criminal responsibility, and it is just from that standpoint that I would like to speak—cases of paranoia in which the delusions were not thoroughly settled, but probably did exist prior to the commitment of the crime, which after conviction and sentence to the hospital or to the penitentiary developed. I have in mind two cases, one convicted of horse stealing and sentenced to five years, another case convicted of larceny. Another case I might mention is a case of homicide, life sentence; one of these cases was a marked case of paranoia and is now in the Central Hospital for the Insane. The patient's delusions are thoroughly systematized and all of a religious nature, he believing that he is Elijah, and his inspirations come through the rocks, etc., and daily he is engaged in his preparation of prophesies. The other case is a case of general paralysis and the patient died after having gone through the regular course. His insanity was not recognized as general paralysis or in fact as insanity for over a year after his sentence, when his maniacal attacks increased and he became a subject of considerable anxiety to the prison officials. The other case is a paranoiac under life sentence, and he is one of those individuals who is being poisoned by the guards and is having noxious gases thrown into his room by unseen forces, and who also has telephonic communication with the devil and his hordes daily. As a result, you can imagine that he can make life miserable for all about him, which he has done since he came to the institution. It was on this account that he was placed in the Hospital for the Insane. It is evident that the attention given to mental diseases in the prisons of our State has been sadly neglected, and it is to be remarked also, that in the paper that accompanied those cases from the prison officials, every form of mental disease is set down as dementia, duration unknown, no symptoms given, and no history at all, and all that we can get is probably from the guard who accompanies them. The appointment of the prison physician is largely political; his attention to details in regard to mental disease is very slight, and all the history we can get is from the guard and from the patient himself.

Dr J. G. Kiernan of Chicago—We have had too little on this subject, especially from American alienists outside of Dr Ball. I remember some communications of Dr Carlos Macdonald of New York based on his results in the Auburn Lunatic Asylum and in part in the penitentiary. In a general way he found the same features of insanity among the inmates, such as delusions, ideas about being poisoned, etc., as has been mentioned, but it seems to me that a number of the cases that the doctor has reported might belong to a good many other categories, for instance, one case which is classified as stuporous insanity might possibly be epilepsy There were no convulsive attacks to be sure, but their occurrence is not necessary in epileptics, there being perhaps but one in a long period and recurrent stupor taking their place With regard to the frequency of insanity in prisons I would state that on one occasion I went through the reports of the Joliet Penitentiary, and discovered that the proportion sent from Joliet to the various asylums was twelve times the ordinary proportion in the State according to State statistics A number of those cases came under my observation at the Cook County institution They had gone to the State institution, their term had expired and they had been transferred to the hospital There was one case in particular which illustrates the point that is often ignored, that underneath a primary hallucination may run a secondary delusion which may impel a man to crime This man had a delusion about witchcraft, he was a negro and a paranoiac and his delusions were based on certain experiments in mesmerism which he had seen performed in his boyhood, and it is a fact that he stole in order to get placed in the penitentiary to escape mesmeric persecution

Another fact, in which I was very much interested, was that the penitentiary officials had reverted to the old procedure of Louré As the majority remember, he used to treat the insane as follows argue with them to show them their peculiar absurdity and delusion and hallucination, and then proceed to douche them, and he undoubtedly checked the exhibition of the delusions of a large number of his patients In a few cases the inhibitions were sufficiently strong to control the patient, but the great majority of his cases when followed up were found to be rendered even more persistent and dangerous than before Another point raised by the doctor which I think does not quite deserve the credit given it, is the attempted differentiation between the insane and criminal The insane do things with the same motive as the criminal You will find insane people stealing from each other, and recognizing that the insane man knows what he is about in that thing You will find that in patients in the wards they will make that distinction themselves between stealing that is delusionary and that which is not Furthermore, it is stated that the insane have not accomplices Here very often you have a central figure, a paranoiac, a principal, and he has a number of accomplices, some of whom may be sane and some insane of a weaker type Take for instance the celebrated religious homicide that occurred in Massachusetts The son of Freeman was ill-balanced and so was his wife, but around them were a number of sane Second Adventists, and some affected with mild paranoia

With regard to the test of insanity in Illinois, we have no test, strictly speaking, other than the essential test of the common law based on each case For instance, if you raise the question of insanity in Illinois, the State must overcome the presumption of insanity and must prove the prisoner insane beyond a reasonable doubt Furthermore, even a prosecuting attorney would not attempt to raise the right or wrong test, pure and simple, the insanity must have overridden the reason and judgment, that is the test in Illinois Of course, as Dr Norbury has stated, the people in charge of the penitentiaries are decidedly careless in their examination, study, history and treatment of these cases One of the physicians in the penitentiary on the witness stand recently did not know the name of the inferior maxillary bone He was a graduate of Harvard, had turned Hahnemannic and was in charge of the Joliet Penitentiary in the interest of a certain clique He is now at the head of a homeopathic asylum in California

Paretic dementia was spoken of I remember in New York three cases came into Ward's Island Hospital, they had been a year in the penitentiary and repeatedly punished for dirty habits, and one of them an old laborer, had stolen socks and shirts in plain view of everybody in a store The boldness made it plainly insanity We found his back criss crossed with flogging In the interests of society I think it is best to adopt the view of considering the criminal of the habitual type as a chronic lunatic and to shut him up for life I remember the case of an ex-policeman who lost a portion of the bone in his head from an accident The traumatism resulted in delusion with occasional periods of excitement His wife gave him quinine on one occasion and got him quieted when the police broke into his room, but the insane man knocked the policeman down with a hatchet, grabbed the policeman's clothes, put his wife's hat on his head and paraded the street with a club He was arrested, taken to the station house, tried, and the jury gave him three years, and the very intelligent judge took off one year on account of the injury to his head The man went to the penitentiary three months and then went to the insane hospital The absurdity of sending such a person to the penitentiary is evident The whole system needs remodeling, but it can be done without any change in the common law which must furnish the basis of all change

Dr Ball—I would like to see the chronic criminal shut up for life, but I do not think it would be well to regard him as a lunatic in order to accomplish that, unless you can prove his insanity As far as epileptics are concerned, I would say that I have as yet very few who have shown any signs of their epilepsy in prison They might have been epileptics, but because of the quiet life they led in prison they never had any convulsions there It is usually the fact that epilepsy has a great deal to do with crime

---

HEMIPARAPLEGIA, WITH REPORT OF A CASE COMPLETELY RECOVERED AFTER ONE YEAR'S DURATION

Read before the Section of Neurology and Medical Jurisprudence, at the Forty fourth Annual Meeting of the American Medical Association

BY L HARRISON METTLER, A M, M D
CHICAGO

In certain lesions of the spinal cord, the prospects of recovery are so much more hopeful from surgical interference than from medical treatment, that an exact diagnosis is of paramount importance Hence every ray of light, however feeble it may be, that illuminates the question of spinal cord localization, should be most carefully cherished Our knowledge of the motor centers of the cord is already sufficiently exact to guide the surgeon in his operations, but the precise limitations of the sensory areas are matters still of much uncertainty A great deal has been accomplished towards increasing our information in this respect by Oppenheim, Westphal, Rosenthal, Eulenberg, Ross, Mills, Osler, Church, and especially Thorburn According to the general concensus of opinion to-day, the decussations of the sensory and motor tracts are such that a lateral focal lesion anywhere below the cervical enlargement gives rise to a *hemiparaplegia*, with paralysis upon one side of the body and anæsthesia upon the other Every instance of an anomalous presentation of this classical picture must be possessed of unique interest, hence I beg to present the following case, which has seemed to me to be worthy of special study

Case —M D , a bright, cultured girl 20 years of age and residing in the western part of Pennsylvania, was brought to me Oct 5, 1890, by Dr C J Steim The following history was narrated to me by the patient herself in the presence of the doctor and her elder sister On the morning of Dec 25, 1889, while walking along the street, she accidentally stepped upon a loose coal-hole cover and fell in such a manner that the left leg passed down into the coal chute while the right was extended out over the pavement She fell completely out with her whole weight Unconsciousness at once resulted, and on account of the free use of narcotics by her medical attendants, she was not fully cognizant of her surroundings until a week after the accident In the meanwhile the hip joint was found to have been dislocated and was immediately reduced There was a considerable hemorrhage from the vagina, and in some way indistinctly described, she was torn Shortly after the accident the left limb began to swell, became extremely painful and was completely paralyzed Poultices and hot applications were employed The fever continued high and with it there was excruciating pain at the back of the head A week later the swelling of the limb entirely disappeared Six weeks after the accident, the faradic current was employed locally to the paralyzed muscles without any improvement In March, three months after the accident, the swelling of the limb reappeared At this time there was no local sweating, no glossing of the skin, no formation of blisters or sores This was the last time that the leg swelled During the course of the year, the right arm enlarged somewhat and became cold and cyanosed This occurred some five or six times At no time were there any symptoms of a similar character in the left arm or right leg There were no cincture pains no eye disturbances, no dysphagia, no dyspepsia, no dyspnœa The bowels remained unaffected, with the exception of a few small bleeding piles which appeared immediately after and seemed to be one of the direct results of the fall The rectal sphincter was very slightly if at all affected The sphincter of the bladder was much weakened Severe metrorrhagia occurred some five or six times, and during the entire year there was a profuse leucorrhea which for a time contained considerable pus Prior to the accident menstruation had always been painful and scanty, but now had become very much more so Micturition also produced severe pain The urine was never voided in normal quantity, but frequently contained a small amount of blood and sediment At times violent pains shot along the spinal column, especially in the lumbar and lower dorsal regions, while a continuous intense pain was felt in the occipital region of the head This latter pain was almost constantly present, but on alternate days became so exceedingly unbearable that the patient was obliged to take to her bed and make free use of anodynes and narcotics

Three weeks before the patient was brought to me, a brilliant stroke of lightning flashed close beside the room wherein she was seated She experienced a most peculiar sensation or "kind of rush" up the spine into the head She fell, became unconscious for a time and continued to be delirious for several days after For a long while she said she could feel a kind of repetition of the shock about every third or fourth day Usually the sensation died out in ten or twelve hours When I saw her she was still subject to intense constricting headaches These seemed to strike from the back of the head forward to the temples, were always worse in wet weather, and as a rule lasted about twelve hours Sometimes the face became puffed and pale, while the eyes would be directed inwards Two weeks after the accident the patient first noticed for herself that her left leg was completely paralyzed and anæsthetic No improvement had occurred in this respect during the course of the year So much for the history of the case

Upon examination I found the eyesight and hearing both good The grasp of the hands was normal and the same in both In the right leg the patella reflex, ankle clonus, muscular movements and sensation were all normal In the left leg they were all completely abolished The line of beginning anæsthesia corresponded quite sharply with that of Poupart's ligament in front, the crest of the left ilium and a line drawn transversely across the left half of the back on a level with the crest of the ilium or fourth lumbar spine Above this line there was considerable hyperæsthesia The limb was well developed, warm to the touch in its upper part, and exhibited the natural color of health Both the cutaneous and muscular sense were entirely wanting The deep insertion of a needle into the tissues, the strongest electric currents as well as simple contact with the skin, were absolutely unperceived So thoroughly did I test for sensation that the possibility of simulation was completely eliminated A similar examination of the opposite leg and of the two arms revealed nothing abnormal in regard to motion or sensation Severe pressure along the course of the left crural and sciatic nerves gave no indication of pain There was no atrophy, as actual measurement showed both limbs to be of the same size With the use of faradaism, a mild primary current produced slow but decided muscular contractions, while the secondary current gave rise to more marked muscular movements The galvanic current produced the usual normal responses I could detect no indication of the reaction of degeneration The electrical examination was not, however, as complete as I would like to have made it, as the patient was suffering from considerable pain in the spine and I did not care to distress her further The distal circulation was slow, and as a result the leg and foot were cold and cyanotic The whole spinal column was so exceedingly sensitive to the touch that its examination was not so satisfactory as could have been desired In the region of the lower lumbar vertebræ it was unusually tender, so that the patient winced and screamed with the pain each time I gently pressed the lumbar spines Between the third and fourth lumbar vertebræ I could distinguish on the left side a small, hard nodule about the size of a pea which was especially painful The distress and general nervous excitement of the patient prevented my determination at that time of the nature of this swelling In the vicinity of the sacrum and coccyx the pain upon pressure was quite unbearable

As a result of this somewhat incomplete examination, I diagnosticated the case as one of incipient meningo-myelitis, with the meningitis as the more pronounced feature at the maximum intensity of the disease focalized on the left side of the lumbar cord I imagined that at the time of the accident there had been a hemorrhage within the spinal column, either in the lumbar region or elsewhere, and that some of the blood had gravitated and formed an irritative clot which in conjunction with the attending inflammatory process was compressing and constricting certain nerve roots from the left side of the cord. With this conception of the case, I recommended a vigorous daily counter irritation of the entire spine, the administration of mercury (blue mass guarded by opium) to the point of ptyalism, the use of the mild faradaic current to the paralyzed muscles, and the employment of cod liver oil by local inunction The treatment was commenced Oct 5, 1890. About a month later, Nov 7, or nearly eleven months after the accident and onset of the paralysis, the patient arose from her chair and walked with as much ease apparently as she would have done in perfect health She stated that a few days prior to my last visit she suddenly felt a kind of tingling and burning sensation, as though the leg had been "asleep," and were recovering, and that this was immediately followed by a complete restoration of its movement and sensation Hyperæsthesia, I found, had replaced the anæsthesia and though it tired the patient quickly to use the limb its power of motion seemed to have been completely regained The tingling sensation was noticed at the same time with a similar sensation up and down the entire length of the spinal cord I found the tenderness of the vertebræ almost entirely gone so that the patient could stand quite vigorous blows upon the back, except in the lumbar region where it was still somewhat sensitive From this time on she ate and slept better and the bleeding of the hemorrhoids ceased On Nov 4, Dr Steim wrote me as follows "Patient is steadily improving and is quite as strong as ever she was" On April 28, 1892, I received this note from the Doctor "I am glad to inform you that Mrs S (she had become married by this time) has never had a single symptom of the old trouble since you saw her In fact her health generally since then has been almost perfect" Again during the summer of last year the Doctor wrote me "The recovery has been perfect and the patient has been as strong, if not indeed stronger than ever before in her life, with the exception of typhoid pneumonia over a year ago"

The unilateral distribution of the anæsthesia and paralysis in this case indicates, of course, a unilateral lesion The presence of the motor and sensory paralysis upon the same side would suggest a lesion outside of the cord proper The absence of any girdle pain of pronounced alteration of the sphincter functions, and of atrophy of the muscles establishes the non-involvement of the gray matter of the card The upper border of the anæsthetic area limits the upper border of the lesion to the level of the first lumbar segment The tenderness of the spine, the fever and other constitutional symptoms resulted of course from the meningitis, which was probably a mere extension of the inflammatory process from the lumbar region upwards The traumatic origin of the paralysis is extremely indicative of a fecal hemorrhage and the presence of an irritative clot would be an all-sufficient reason for the inflammation of the membranes The hemorrhage was probably subarachnoid The transitory symptoms which arose during the course of the year in conjunction with the upper regions of the cord may have been due to a number of smaller hemorrhages of which the blood may have gravitated and so produced a large, irritative clot along the line of the lumbar segments and in the meshes of the cauda equina The chief difficulty in this explanation, however, is the completeness of the anæsthesia from the very beginning of the paralysis, for such a sudden and complete anæsthesia usually follows a lesion in the substance of the cord itself or complete severance of the nerve roots When nerve roots are compressed by hemorrhagic clots or meningeal adhesions it is more customary for the anæsthesia and paralysis to be preceded by pain, hyperæsthesia, paræsthesia and spasm Furthermore, with anæsthesia dependent upon destruction of the posterior nerve roots, there is generally very decided atrophy of the corresponding muscles, especially if the lesion involve the root ganglion or that part of the root external to the ganglion

It must be admitted that there are certain features about this case strongly suggestive of hysterical hemiparaplegia They are for instance the sex and age of the patient, the location of the paralysis (hysterical paralysis being most frequent in the left leg) the absence of any considerable atrophy, the apparent preservation of the rectal with but slight involvement of the genito-urinary functions, the association of the paralysis and anæsthesia in the same area and the peculiar distribution of the anæsthesia which corresponded so closely with Charcot's well-known limitations of anæsthesia in hysterical paraplegia Against the hysterical hypothesis, however, I place the traumatic origin of the motor and sensory paralysis, the absence of all other hysterical symptoms during this or any previous period of the patient's life, the prolonged duration of the paralysis and anæsthesia without the slightest modification, the absence of the hysterical temperament, the completeness of the anæsthesia and the perfect insensibility of the nerves to the strongest electric currents, the hyperæsthetic zone just above the level of the anæsthetic area and the complete restoration without the slightest subsequent reappearance of any of the old symptoms Furthermore, the upper limit of the anæsthesia posteriorly corresponded with a horizontal line drawn across the back on a level with the fourth lumbar vertebra, and not with the line of hysterical paraplegia which Charcot says, "follows the insertion of the muscle of the buttocks exclusive of a V-shaped area over the sacrum"

In the *American Journal of the Medical Sciences* for July, 1892 Starr reports a case (No 5) possessing many points of similarity with our own Briefly stated, the patient was a woman, 28 years of age, who was well until May, 1889, when after a day of fatigue she was suddenly seized with severe pain in the sacral region and in the back of both thighs, with retention of urine and feces and with a sensation of numbness over the lower sacral region, perineum and vagina The urine and feces were moved with much difficulty The sphincter ani contracted on the finger The knee-jerks were exaggerated The plantar and gluteal reflexes were normal, and there was no tendency to bedsores, no tenderness of the back, no girdle sensation nor anæsthesia of the legs When examined again in Feb 1890, there was beginning muscular weakness in the left leg and a diminished response to faradaism, without atrophy There was still some pain in the back and in the left leg constantly but more especially in the left ilio-inguinal region There was still no girdle sensation, spinal tenderness or bedsore The area of total anæsthesia had increased There was slight impairment of the tactile sensation on the outer side of the leg below the knee and on the back of the thigh from the anæsthetic area downwards The case was not so far advanced as ours, but in the association of its symptoms closely resembled it The diagnosis of Starr was that of a hemorrhage into the conus medullaris and lower sacral segments of the cord He suggested that this hemorrhage had lighted up a chronic meningo-myelitis and as this advanced slowly upwards, it had increased the symptoms

Starr and Lloyd's case (No 11) in the same paper, was one of compression of the cauda equina producing a localized paralysis and limited anæsthesia in the right leg There was a fracture of the lumbar vertebræ, followed immediately by a paralysis and indefinite area of anæsthesia in the right leg A year later there was marked deformity at the third lumbar vertebra, paralysis with atrophy, reaction of degeneration of most of the muscles of the right leg, anæsthesia down the back and outer side of the same limb In view of the diagnosis of compression of the cauda equina at the third lumbar level, Dr Lloyd operated and removed the second and third lumbar spines and laminæ with ultimate recovery of the patient. The point of significance in this case is the association of the anæsthesia and paralysis, which is explained here by the limitation of the lesion to the cauda since the spinal cord proper terminates at the first lumbar vertebra. The absence of the sphincter symptoms would exclude involvement of the corresponding nerve centers, which Starr finds from two of his cases to be located in the "lower two segments of the cord," a fact which has been confirmed by autopsies in the cases of Kirchkoff, Westphal, Oppenheim and Herter, and in the cases of Rosenthal, Bernhardt, Eulenberg, Mills and Huber. It is always difficult, except in fracture cases, to differentiate lesions of the cauda from those of the cord, and Starr takes the position that it is "questionable whether, except in cases of fracture below the first lumbar vertebra with displacement of the vertebræ any sharp line of distinction between cord and cauda lesions should be attempted." It is to be hoped, however, that some day our knowledge may permit us to make such a differentiation.

In connection with the case I have reported, the question arises as to the possibility of there being a unilateral paralysis and anæsthesia in the same limb, as a result of a single unilateral lesion of the cord. In other words, Is there such a thing as a true hemiparaplegia produced by a focal lesion in which the paralysis and anæsthesia are not crossed? The textbooks almost universally answer this question in the negative. Ranney[1] says "The muscles below the seat of the lesion are paralyzed on the side of the body corresponding to the exciting cause and the skin is sometimes rendered hyperæsthetic, while the integument of the side opposite the lesion is deprived of sensibility." In his "Lectures on the Nervous System," he furthermore most emphatically states that "should symptoms of anæsthesia appear upon the side where the motor paralysis is present, you may regard it as conclusive evidence that the exciting lesion is progressing and the opposite lateral half of the cord is being involved to a greater or less extent." Seguin[2] writes that "hemiparaplegia is a rare variety in which one lower extremity is paralyzed while the other is anæsthetic."

Mills[3] says that "motor paralysis occurs in the leg of the same side and anæsthesia in the trunk and leg of the opposite side." So authority after authority might be quoted, all stating the same truth. They insist upon the crossed nature of the symptoms. The sensory fibers, after passing through the posterior nerve roots, enter the gray matter of the posterior cornua and at once cross to the opposite side of the cord through the posterior commissure and then continue their course upward to the cerebral cortex. In the upper part of the cord the fibers decussate almost immediately after they enter the posterior cornua but farther down the cord we find them running for a short distance more or less vertically in the side of the cord and in company with the corresponding nerve roots before they pass to the opposite side. In other words, the decussations are relatively higher than the corresponding nerve roots the farther we proceed down the cord. In the words of Gowers,[4] "The decussation of the sensory tract is not immediate but occurs somewhat above the entrance of the nerves." This, I believe, is of some importance in the diagnosis of our case, for as Gowers again remarks, "A lesion in one side of the lumbar enlargement often affects sensation on the same side as motion because it damages the sensory path before it has crossed." In our case I can not think the anæsthesia was due merely to compression of the nerve roots by the meningeal trouble, because it came on so early and suddenly and was not preceded by the usual hyperæsthesia and initiative signs of local meningitis. In fact, the whole set of meningeal symptoms seems to have been of later development. Nor can I think that the posterior nerve roots supplying the anæsthetic area were themselves torn or injured in such a way as to be alone responsible for the loss of sensibility, because the anæsthesia lasted too long to be so quickly recovered from. Torn nerve roots are not usually restored in a few weeks' time by mere external counter irritation and the administration of mercury. I assume, therefore, that the sensory tracts must have been injured somewhere near the periphery of the cord, and that this must have been before the tracts which transmit tactile impressions were separated from those which carry the sensations of pain and temperature since all forms of sensibility were abolished from the anæsthetic area.

According to the most recently constructed tables of segmental spinal localizations, the lesions could not have extended higher than the first lumbar segment. The paralysis and anæsthesia stopped quite abruptly at Poupart's ligament anteriorly and the upper part of the buttock posteriorly. There were no girdle pains whatever, either of the body or the limb, to enable me to determine the level of the lesion more accurately. If the original trouble were a subarachnoid hemorrhage, as I fancy it must have been, the blood may have gravitated to the lower part of the spinal column and involved the fibers of the cauda without doing any special damage to that structure beyond compressing it. A clot may readily have formed on the left side of the cord opposite the lumbo-sacral region, there exerted a pressure sufficiently deleterious to prevent the transmission of the motor and sensory impulses in the corresponding tracts as they passed along near the circumference of the cord, and also to have lighted up a meningitis which gradually extended along the whole column and even implicated to a slight degree the membranes covering the brain especially in the occipital region. Such an explanation is the most reasonable to my mind and harmonizes most satisfactorily some of the discordant symptoms of the case. If such be the correct explanation, the case indicates that we may have a hemiparaplegia, especially from a lesion in the lower part of the cord, in which the anæsthesia and paralysis appear upon the same side of the body. Further investigations are needed, however, upon this point, though I feel sure that the textbooks are somewhat too dogmatic in asserting that in all cases hemiparaplegia is a paralysis of one-half of the lower part of the body with anæsthesia of the opposite half.

WHAT SHOULD CONSTITUTE LEGAL RESPONSIBILITY, IN THE MEDICAL SENSE, IN INSANITY?

Read before the Section of Neurology and Medical Jurisprudence, at the Forty fourth Annual Meeting of the American Medical Association

BY LANDON CARTER GRAY, M D
PROFESSOR OF NERVOUS AND MENTAL DISEASES IN THE NEW YORK POLYCLINIC

It is high time that we medical men should impress upon lawyers the fact that the question of legal responsibility in insanity should not be determined by laws, but by facts As it is, the belief of English and American jurists is that which is embodied in the statutes of almost all of the States, to the effect that knowing the nature and the quality of an act and its consequences should be taken as a full test As every one in this room will know who is acquainted with the insane, this dictum is worse than ridiculous, for it is false, as there are very few forms of insanity in which the patient is not fully aware of the nature, quality and consequences of an act which he or she may commit Out of this definition of a legal responsibility has grown the legal belief that a person is possessed of testamentary capacity when he or she can talk in a sufficiently intelligent way to evidence a knowledge of the nature, quality and consequences of the will which he or she may be making Indeed, so ill defined is the definition of testamentary capacity that I have frequently suggested to my legal friends that the greatest certainty of having a will admitted to probate would be to establish the insanity of the testator or testatrix Let us briefly examine the facts, not the statute law, about insane patients

All the types of insanity that have been demarcated up to the present time can be classified by

1 The moods
2 The presence of hallucinations
3 The presence of delusions
4 The coexistence of the neuroses
5 The coexistence of organic disease of the brain
6 Traumatic causation
7 Causation from excessive use of narcotics
8 The mental disturbances occurring induced by disease of non-nervous viscera

Mania and melancholia present as their basic symptoms alterations of mood, the former being an exaggeration in slighter or greater degree of good spirits, and the latter presenting the converse When there are hallucinations as the chief symptom around which all the others cluster, there is hallucinatory insanity A persistent delusional condition, at first consisting of delusions of persecution, to which in the course of time are added delusions of self-exaltation, constitutes that type of insanity to which has arbitrarily been given in latter days the name of paranoia, formerly designated delusional insanity Magnan, it should be said by-the-by, maintains that in many cases of this type the delusion of persecution is never succeeded by that of self-exaltation or grandeur Such neuroses as hysteria and epilepsy lend a peculiar imprint to mental disturbances occurring in the course of them These insanities, whose pathology is yet but dimly understood, are happily embraced by the Germans under the generic term of the psycho neuroses, to distinguish them from the mental disturbances which occur in the course of such organic diseases of the brain as hemorrhage, thrombosis embolism, meningitis, tumors, intra-cranial syphilis, and that slow, remittent, insidious encephalitis which is known as paretic dementia or general paresis, and which is characterized by the commingling of characteristic mental symptoms with physical ones Insanity of traumatic causation is usually an insanity due to organic cerebral disease produced by trauma, or to epilepsy from the same cause We are all familiar with the mental disturbances from alcoholism, cocainism, morphinism or chloralism I have but little faith in the frequency of so called reflex insanities, i e, those produced by slight lesions of non-nervous organs, but no one will attempt to deny that mental disease can occur from the widespread vascular, textural and nervous derangements of nephritis, pyeluria, hepatitis, typhoid, peritonitis or septicemia[1]

Of all these varieties of mental disease, the ones that most frequently give rise to medico-legal questions are paranoia, mania, melancholia, general paresis and the insanities arising from the excessive use of narcotics In paranoia the mental condition is, as has been said, a delusional one, generally at first of persecution, to which in the course of time is added another of self-exaltation or so-called grandeur But these delusions are perfectly logical, and the memory and the reasoning powers are intact In mania there is chiefly an alteration of mood, so that the patient seems more vivacious than usual, and in the subacute form this exhilaration may be so slight as not to rise above the level of high spirits, while in many instances delusions and hallucinations are not present, and in most there is the same preservation of the reasoning powers and the memory as in paranoia In melancholia the alteration of mood is that of depression, but in a vast number of cases, constituting the bulk of mental diseases observed in general practice, this depression is so evanescent and slight as not to be greater than that caused by indigestion, a disagreeable bit of news, an unpleasant emotion, and a thousand and one other disturbing factors in life, while in melancholia, as in mania and paranoia, the reasoning powers and the memory may not be at all affected In the early stages of general paresis and in its remissions the element of stupidity is so slight that it can often only be detected by an observer made keen by experience In the mental alterations caused by undue indulgence in narcotics there may only be present some hallucination, some delusion or some unbalanced judgment that can not be evidenced except by observation of the patient through days, perhaps weeks In all these forms of insanity, therefore, it is absurd to test the patient's knowledge of the nature, quality and consequences of an act by merely questioning him For instance, Dougherty, the so-called lover of Mary Anderson, murdered a young Dr Lloyd of the Flatbush asylum, because he believed that Lloyd was one of the agents of a system of legal procedure that had done him grave injustice, and he was proceeding to murder a supreme court justice and about a dozen State and county commissioners of charities whom he thought to be agents of the same legal machinery, when he was fortunately arrested All this murderous action had arisen from his delusion that Mary Anderson loved him and that the world had conspired to prevent his going to her Yet when this man was tried for murder, he insisted on taking the witness stand himself, and stating that he knew perfectly the difference between right and wrong, and the nature, quality and consequences of the act that he was doing when he shot Dr Lloyd The jury found him insane, but there was so much doubt in the public mind that a commission was appointed, of which I was a member, and he was again adjudged a lunatic Judged by his general intelligence—indeed, by his own statements—this man understood well what he was doing Nevertheless, it was evident to every one that his delusions so warped his mind that he did not realize, in the true meaning of the word, what he was doing Nor do I believe that any insane person has a true realization of his acts Never mind how small the flaw may be in his mental machinery, it may be quite sufficient to warp the mind The law clings tenaciously to the old idea of lucid intervals, but alienists nowadays no longer believe in them, and the imperfect science of a former day probably mistook remissions for them No one can catalogue the human mind, except in a very general way So far as we have been able to analyze it clinically, however, it may be said to consist of sensations received by a conscious intelligence in a way that experience has shown to be normal to the human being, as well as of actions springing from this intelligent recognition of sensations If the moods are altered, as in mania and melancholia, there can be no intelligent recognition of sensations If the sensations are faulty, giving rise to what are technically known as hallucinations and illusions, the intelligence is corrupted by false news traveling in over the perverted nerves from the various tissues of the body If there are delusions, the intelligence, in proportion to its intelligence, is the sport of these delusions If the intelligence itself is confused, causing what we call stupidity, who can venture to prophesy what the mental outcome will be? If erratic actions arise from diseased brain cells receiving normal or perverted sensations, these very actions are evidence of a warped mind I could make this short recital of instances much longer if I were to go into all the clinical proof at my command of how a seemingly partial mental defect is really a general one

---

[1] In all these types of insanity hallucinations illusions delusions and alterations of mood may occur but it is the predominance of one or the other of these symptoms that is the basis of classification

But I think that you will agree with me that the only safe test of the legal and testamentary responsibility of a man lies in an answer to the simple question Is he insane? If he is, he is not legally responsible for his acts, nor has he a testamentary capacity Nor should this question be determined by questions put by lawyers, by fine-spun metaphysical definitions of mental aberration or by evidence of seemingly intelligent acts and motives, but rather by examinations made by physicians competent to decide whether the man in question is suffering from one of the recognized types of mental disease When a physician testifies that a man is sick with some disease affecting a non nervous organ, no lawyer would dare to raise a Homeric roar of laughter by asking him for a general definition of sickness, instead of having him localize the disease and then making him state the usual symptoms of this malady Is it not true that the same common sense should be applied to mental diseases? I think so, most assuredly

DR J G KIERNAN—It seems to me that Dr Gray's strictures are much more applicable to many of the eastern States and perhaps a few of the western, than to all Now in Illinois, although the practice has slightly departed from the decision enunciated in New Hampshire, and which is practically the outcome of the old common law before the ecclesiastical lawers got to fixing notions about responsibility, the principle still holds that each case is tried on its merits In the next place the State must prove beyond a reasonable doubt that the man is insane, if the defense raises even a suspicion of insanity In New York the right and wrong test was swung into the code under the influence of David Dudley Field, with the old notion of deterring the insane from crime It so happened that David Dudley Field himself had a relative who committed a crime and under that same test was sent illegally to an insane hospital Even in New England we find judges on the bench applying the strict letter of the code in trying such cases as that of a woman who has killed her child with the full knowledge of the consequences of the act It seems to me that all these cases can safely be left in a great degree to evolution The more you attempt to express matters in the statute the more you tend to crystallize them and interfere with the due course of things The tendency is directly opposite from what is usually assumed The proper course is to deal with each case on its merits and not to lay down any general rule, and that is the old doctrine of the common law Even old Sir Matthew Hale's divisions of insanity are correct, except when he is influenced by the ecclesiastical law notion of responsibility, when he gets sadly twisted

DR FRANK R FRY—I would like to ask what the Doctor means by having established a suspicion of insanity in a legal way, so that the case might be presented on that basis I am not familiar with what the method is in the State of Illinois

DR H M MOYER—The practice in Illinois is under the common law, and it seems to me from a careful study of the statutes of other States and those States like New York that have codes, that the practice that holds under the common law is far preferable in these cases The proceeding in Illinois is substantially this a person that is charged with crime is indicted Then it becomes the duty of the State in the first instance after indictment when the person is called upon to plead, to accept the plea of not guilty, if insanity is to be the defense The State then goes on and makes its own case as to the crime Of course that is perfunctory where it is practically admitted that a crime has been committed Then the defense comes in, if there is no defense on the merits, if insanity alone is rested upon, to prove the mental condition of the patient What is meant by the suspicion raised? It is this no matter how much or how little is raised as to the mental condition of the patient it must be overcome by the State, and the rule of the law that is given to the jury is that the State shall make out in rebuttal after the defense is put in, and prove the person sane beyond a reasonable doubt, which means that every scintilla of evidence tending to show that the patient is insane must be overcome by proof We have tests that are propounded and used, and sometimes they go into our instructions but the common law is so construed in that State that the tests are practically inoperative, because there is always an instruction asked on the part of the defendant, taking all the facts of the law into consideration, does the jury find that the reasonable doubt is in favor of the prisoner That brings it down to a matter of the jury entirely I will say regarding Dr Gray's paper that it seems to me that he is a little in error on one point He says that insanity if present should absolve a man from the consequences of his act and should not entitle him to testamentary capacity The rule of common law as most States give it, is that there is a different degree of mental aberration to absolve from responsibility for a criminal act than will permit a man to will his property The rule of the law in determining whether a person has testamentary capacity or not is, Did the person know and comprehend the manner in which he intended his property to descend and to whom, if he comprehended these two factors it has generally been held that he has testamentary capacity Certainly, it admits of a degree of mental defect far greater than would excuse a person for committing a crime I think that we shall never reach any better basis than that of the common law, although there are faults that can be found with it in some respects It is to be remembered as the darkness of mental disease settles down on a man's mind it does so gradually, there is the beginning of twilight settling down into hopeless dementia and all stages between those, and there must be an arbitrary division fixed somewhere, and I do not think that arbitrary division can be fixed by medical men or by lawyers Nobody can fix it, because it is the same thing as after sunset, when the sun goes down, there is a period of all shades of twilight into absolute darkness No one can say where day leaves off and night begins absolutely So in mental disease, some such flexible rule as is adopted by the common law I believe to be as near perfection as we shall ever get in dealing with the matter of insanity as a defense for crime

Dr L C Gray—I did not know that the State of Illinois had a law so entirely different from that of New York, but certainly the textbooks of law do not give any such rule as seems to be current in Illinois, and the test taken altogether of the American States is the test of the individual knowing the difference between right and wrong measured in the consciousness of the act There are many absurd laws which judges will attempt to get around by permitting a laxity in their application, but as long as those absurd laws remain on the statute book, some martinet of the law may make you follow the hard and fast line Whatever the practice may be, the statute law can always distort the practice The fact is that in the majority of our States the old test of responsibility of right and wrong and the knowledge of the nature and consequences of the act remains, we in New York are constantly asked to solve that question by the testimony put at our disposal and it leads to all sorts of fraud and injustice, whereas a much simpler test would be simply, Is the man insane? It is no answer to say to that, that we do not know all the forms of insanity We can make out the majority of cases that come before the courts It is better to have some test than not to have any at all, as we have now, even though that test is not a perfect one

I should disagree with Dr Moyer in regard to the gradual obliteration of the mental faculties and the ultimate passage into dementia, because there are different forms of insanity, acute and subacute and chronic, and their onset may therefore be very sudden, or on the contrary gradual The onset of transitory frenzy is very rapid indeed Then again a great many forms of insanity like paranoia do not pass into dementia, and a great many of the cases of mania and melancholia have no inherent tendency toward dementia, so that I do not think that that line of argument will exactly prove to be the safe one I do not think that any man's mind that is affected by disease is a safe mind to be left to dispose of his own goods and chattels The statute law or any law made by sane minds, can do better than the mind of any insane man no matter how slightly affected, and you can not tell with all the myriad reflexes and connecting causes, how much of a given act or of a given opinion has been made up by diseased action and diseased reflexes It is utterly impossible for any man to unravel that knot, and taking the common sense of it, is it not much safer to trust the disposition of that property to the law that has been thought over by competent and educated lawyers and which is so good that many able lawyers nowadays prefer to leave their property to be distributed by the statute law, rather than to say that the individual shall have the right to disinherit her nearest relatives, as was the case in the city of Buffalo of Mrs Millard Fillmore, who disinherited every legitimate heir, to encourage a pseudo science and religion, by giving her property to the city for all sorts of wild purposes, leaving her heirs in absolute poverty It is no use to discuss what would abstractly be the best, but what is in the majority of cases an improvement on the present system, which is no system at all, and which was simply a wretched system when originally proposed, and a disgrace to our present civilization, inasmuch as it takes no ground whatever as to what has been done in psychiatry for the last fifty years

LEGAL CRITICISM OF MEDICAL EXPERT EVIDENCE

Read before the Section of Neurology and Medical Jurisprudence at the Forty fourth Annual Meeting of the American Medical Association

BY CLARK GAPEN, M D
OMAHA, NEB

A recent writer in the *Columbia Law Times* somewhat intemperately characterizes medical expert testimony thus "Of all the cant that is canted in this canting world expert medical cant is the most pernicious Of all species of evidence offered in a court of justice, none, not even the testimony of the accused, when a witness on his own behalf is more freighted with suspicion than is the evidence of the medical expert" And quoting Lord Campbell he adds "They come with such a bias on their minds to support the cause in which they are embarked that hardly any weight should be given to their evidence" The writer then goes on to say that the medical expert in his first estate was a formidable ally of justice, but that the corruptions of the world have demoralized him "These doctors," says he, "are of the earth, earthly, and their virtue, if not an unknown quantity is flagrantly insufficient in quality" He charges our profession with a vast amount of "very gaudy and unembarrassed lying," and believes the average doctor to be possessed of such an exalted opinion of his own accomplishments and such a corresponding contempt for antagonistic views as to seriously cripple his judgment "This serene Olympian" in the opinion of our author, "mounts the witness stand with a chilling and withering hauteur, a composure and touch-me-notishness that belong only to the elect" This intemperate philippic against expert evidence has recently passed around the newspapers and the echo is heard in multitudinous editorials on the subject

"Doctors," says one, "seem to regard their profession in such cases much as lawyers do theirs They are expected to use their knowledge and skill as lawyers do theirs to aid in the conviction or acquittal of the accused The result is the discredit of expert testimony It is hardly more valuable than the asseverations of the attorneys" Nor are these criticisms confined to recent times, or the newspapers and legal journals No less an authority than Justice Grier of the Supreme Court of the United States said in an opinion written many years ago "Opposite opinions of persons professing to be experts may be obtained to any amount, wasting the time and wearying the patience of the court and perplexing instead of elucidating the questions involved in the issue." Chief Justice Chapman of Massachusetts may also be quoted as saying that "experts might be found to testify to any theory however absurd," and the learned Chief Justice Redfield of Vermont, author of the best treatise on wills extant says "Experts are beginning to be regarded much in the light of hired advocates, and their testimony as nothing more than a studied argument in favor of the side for which they are called." Justice Davis of the Supreme Court of Maine went farther than the others, however, when he said "If there is any kind of testimony that is not only of no value, but even worse than that, it is that of medical experts." With all this weight of very learned testimony against him we might reasonably conclude, that the case of the medical expert witness was effectually disposed of. We still find him, however, though somewhat disfigured yet an important factor in the various litigations that arise. There can not transpire a business transaction of any kind, an act civil, or criminal, of which the courts have jurisdiction but may involve some question demanding the attendance of the medical witness. Criticisms such as I have quoted from bench and press are not, however without foundation in fact. Some to be sure are grounded in a purely ignorant and asinine dislike of another profession. Some due to the bitterness of defeat. Corporation attorneys, no doubt feel themselves often aggrieved and justified in doubting both the honesty and value of much so called medical expert testimony. Let us look at the causes underlying these conditions and ascertain if possible what are potential on our side, and what active on the side of the legal profession, to bring about this unhappy state of mind in our brother profession and lay upon ours this stigma. The first and perhaps most potent cause lies with the attorney himself. He has a case—is perhaps unprepared both in respect to his knowledge of the case and a sufficiency of evidence. He casts about for some bright medical man to assist him. I am afraid he does not always care most to know how unimpeachable is the man he selects. What he wants is help. Honest help if he can get it—if not, help. He wants some one to help him make out his case, which usually means that he has a mark set up and he wants some medical man to swear at it. This matter of the oath is possibly seen from somewhat different points of view by the lawyer and the doctor. Theoretically the oath is to the lawyer a sort of fetish. In all his books and lectures, it has been enough to say "under oath" to express to his mind the highest degree of certainty and solemnity. I doubt if the physician and layman has any adequate conception of the feeling inspired in the breast of the lawyer by the term "under oath." But in some other respects the law in practice does not maintain so high an ideal of professional morals and conduct. It is not generally regarded to be to the lawyer's discredit that he resort to almost any means of winning his case. In legal practice that is constantly done which would make even the doctor shudder for the welfare of the soul of his professional brother in the law. It may be that the great and solemn phrase, "under oath" is not often enough uttered in the hearing of the student of medicine. It may be that he has not in the language of the Buddhist, "gone into the forest," and seriously meditated what it is to be a witness under oath, but certain it is that he has not been able to see such a vast difference between telling a lie and swearing a lie. He that does the one, will find a way to do the other. When the doctor is on the witness stand, however, the lawyer (on the other side of the case) experiences a sudden expansion of his conception of the gravity and importance of strict adherence to the naked truth. But when the witness is his, the lawyer is too apt to become willing for him to strain any part of his conscience that will help the case. If the doctor is weak enough, he will be thus used again and again, but the very attorney that uses him will cherish a contempt for him. The solemnity of the oath should not be undervalued nor its importance as a safeguard in evidence be lightly considered. But the truth is the truth and at all times most sacred. "Every place a temple" to truth and justice. In the large majority of cases involving medical, surgical or psychological questions the attorneys are merely "crammed" for the case. In the very nature of things this must be so, for it is manifestly impossible for any mere lawyer to have other than a very partial view of the questions involved. He may have acquired knowledge, but he can not have acquired that experience which vitalizes knowledge. It is oftentimes very laughable to realize how partial this view is. Only the fact that the opposing counsel is equally ignorant and the jury still more unenlightened keeps the case from breaking down. I have sat throught a trial for manslaughter and heard a bandying back and forth of medical and surgical terms by the opposing counsel that would have kept a medical college in a roar. But with this partial view the lawyer sets up a theory of the case for the poor doctor to work to, and he is expected to help it on whether it would have been his view or not if left to himself. The course chosen, everything must bend to it, everything must be done to help it on, and everything suppressed that will in any manner retard. The trial of the case then becomes a mere contest of wit in adducing and suppressing evidence. Of course this is all wrong and no one knows it so well as the well informed lawyer. It is not common sense, much less common justice. Any intelligent member of the bar will tell you that as at present conducted, the trial of a cause involving a medico-legal question is a mere farce, as compared with the trial of a cause involving a pure question of the law. The reason is simple. The lawyers trying the case understand the questions of law involved and it is Greek to Greek. But they neither know nor understand questions in medicine, surgery psychology or toxicology. This great fault in our jurisprudence is probably in the main due to the jury system which we have not yet outgrown, and which we are not likely to outgrow for some time to come, notwithstanding the fact that no country in Europe has a jury but England. Another cause is the desire of some lawyers to pose before John Smith as a man who knows everything and to hear John remark that he (the lawyer) knows more medicine than all the doctors. Of course John knows. I believe it will be found an invariable rule that the greater the lawyer the more will he seek and value assistance by those specially trained and informed. The lawyer that merely aims to pose before Smith and expects to win his case by hook or by crook needs little counsel. It takes a fair sized lawyer to realize that he doesn't know it all and is merely making a fool of himself when he attempts to utilize knowledge of which he has only a mere smattering. The condition referred to can be corrected only by a change in the statutes of the several States relating to the selection and calling of experts. The expert should be selected by the court from lists presented by the counsel, as advisory to it, and wholly with reference to his special knowledge of the question involved, which question should be submitted after the evidence is all in, in the form of one or more hypothetical questions based upon all the evidence. "Opinions on the case" should not be tolerated in any form. They are a plain invasion of the province of the court and jury. We should not, however, conclude that the trouble lies wholly with the law or the lawyer. A large part lies with us and in our faulty systems of medical education. We educate the student in medicine, surgery, bacteriology, pathology, etc., and forget the all important fact that he is to become a *citizen* of a community and that great and peculiar responsibilities resulting out of his professional duties and relations are to be laid upon him by the law. The very first case to which he may be called may involve a grave legal responsibility. It may be a case of murder or poisoning or involve a question of mental competency or responsibility. Nearly every medical college has a so-called chair of medical jurisprudence, but what does it teach? It usually repeats the mummery of some textbook of the science, merely rehearsing in a weak way what has been better taught in other departments by teachers specially qualified. The instruction is uninteresting to the student and valueless. What should be taught are the special facts of medico-legal science, not taught elsewhere, and the legal duties and responsibilities of the practitioner in his triple relation of *citizen, practitioner of medicine* and *expert*. In short he should be given a forecast of the legal experiences he is about to encounter in the many and varied relations upon which he is about to enter. If he practices at all he must come into contact with law in some manner. This is not a kind of practice he can choose or let alone. He should therefore be especially and carefully taught his responsibilities and duties under the law. He should be taught to know when he is placing himself in a position that will or may make him a witness, and his eyes should be opened to the things he should see and note to make him a reliable and useful witness. He should also know *how to be a witness*—how to prepare and demean himself, that he may not be disconcerted by the ordeal or reflect discredit upon himself and his profession. He should know that to be frankly truthful, to be calm, self contained, direct and plain in his statements, simple and non-technical in his language, avoiding pomposity and high sounding phrases is to be a good witness and that the converse is to be an ass. Being untaught in these important practical matters he goeth forth as a lamb for the slaughter. I have known a middle aged physician filling a high position, nearly ruined professionally and an exceptionally well-educated young physician driven out of a city by the want of the knowledge of which I am speaking. That students go forth unequipped in this regard is not their fault. Twelve years of teaching both law students and medical students has taught me that law students are always interested to know something of medical science, and medical students eager to know that part of the law which concerns them. Another cause of the disrespect of medical expert evidence is the common custom of participating both as counsel and witness in the trial. This, too, is the mistake of the lawyer. He knows better. The doctor does not. A lawyer shuns the witness stand and especially in a case in which he is counsel. It is universally conceded to be bad practice for counsel to testify and important evidence will often be sacrificed rather than violate this rule. Only in extreme cases is it countenanced. But the lawyer not only permits, but encourages the physician to do this very thing—act as a witness and sit by as counsel with the effect of impairing the confidence and respect of court, jury and public in him and in his testimony. It is a practice to be condemned in no uncertain terms. Another grave source of impairment of confidence is the fact that there is a large and growing class of medical men who pose as professional witnesses—expert swearers, so to speak. Men who are tempted by the publicity and the emoluments to frequently participate in trials as experts, even where they are not specially qualified to be experts either by learning or experience. The courts themselves are to blame for this. It is within the discretion of the court whether or not a given witness is expert in respect to the particular question involved. The adjudications are very satisfactory on this point and only need to be lived up to. The legal rule and definition of expert is "one instructed by experience" (Bouvier.) To be competent the individual must be in some way peculiarly qualified to speak on the subject (3 Bosworths, N. Y. 7.) The fact of special skill must be established or witness rejected (Ordronaux, 126.) A court may hear evidence to satisfy itself that a witness is really what he assumes to be before admitting him to testify (6 Rand, 704—12 Alab., 648—1 Munn, 125). It is often said that the medical profession is narrow, both in its scope and tendency—that the doctor gets rutted and never knows or thinks anything else than medicine and each year grows narrower. I believe this to be in the main unfounded, but in respect to knowledge of the law, which every man is presumed to know, it is true. It is not to the discredit of the lawyer that he knows many things other than the law. Why should it be to the discredit of the doctor that he knows something besides medicine? Are we not too modest in this respect? We should not forget that some of the greatest lawyers this country has produced were first doctors. The late Justice Miller, of the Supreme Court of the United States and Judge Dillon are examples. May we not do something to dissipate the idea that we of the medical profession are not to look beyond the horizon of our own calling?

DR. J. G. KIERNAN—There are two or three points with which I agree and others in which I dissent from Dr. Gapen. There is a certain class of lawyers including criminal lawyers who are exceedingly high, while others are about as low down as possible. That class of lawyers does not, as Dr. Gapen has stated, think the less of a man because he lies. I have known a specimen of that stamp denounce every doctor who appeared against him, as venal, even though he had approached every one of those doctors and attempted to retain him in his case. Furthermore, it is a growing practice among a certain liberal set of criminal lawyers to form their theory through the aid of a physician in a given case The physician forms a theory of a case on the facts stated by the lawyer, and the testimony agrees generally much more thoroughly with the theory so formed than with the hit-or miss method usually employed That was the case with the medico-legal issues arising in the Cronin matter In that case the attorneys consulted a physician who never appeared in the case and who made up the minor theories on which the blood question and the other questions were afterwards proven, and every one of the questions drawn up by him were laid before the experts afterwards With regard to the proposed remedies by the courts, I would say that it seems to me that the true remedy has been suggested by Dr Gapen, namely, instruction in our colleges in the first place, that in criminal cases every circumstance tending to prove innocence must be taken into account, and furthermore everything must be construed in the light of innocence, and guilt proven beyond reasonable doubt We find every day, physicians considering certain cases as exceptional and therefore not taking them into account, but swearing positively to a certain set of facts to which there are exceptions On the other hand, the point should be brought out that the question is one of preponderance of evidence merely in civil cases, and instruction should be given in that line as well as in criminal cases and the distinction clearly shown True medical jurisprudence is really not taught in our colleges, but in the place of it the Gradgrind method is used of pouring in mere facts

THE CHAIRMAN—I think many of the reader's points are well taken, still I do not believe that some of his remedies are practical It is a frequently made suggestion, that the trouble with reference to expert testimony and the evils nnected therewith, could be overcome by making the ts the advisers of the court The method suggested r Gapen is one, others have been suggested, but in main they are on the same principle It has been sug sted to have official court experts A very considerable xperience in medico-legal matters leads me to believe that this plan would not work any better than the present except, perhaps, occasionally, at least, I am doubtful of it, and I believe as Dr Kiernan has said, that probably in Europe they are finding it somewhat of a failure It would be impossible for court experts to give opinions in an open jury trial, for or against a man, without the party accused being allowed full opportunity for expert and every other sort of defense Otherwise, it would be taking away the rights of the individual, and simply would result after a time in most of the cases that the court expert would be submitted to the same sort of examination and cross-examination as anybody else, and with this additional difficulty in many cases that the court expert would be a political or personal or some other sort of obnoxious appointment, nor would the difficulty be removed by allowing the judges to call in in special cases a court expert I do not see how we could get around the difficulty in this way, although it has often been suggested I think I understood the doctor to say that opinion should not be tolerated

DR GAPEN—I used the expression, "opinion on the case," and I used it technically, not in the ordinary sense

DR KIERNAN—I understood that you meant hypothetical opinion

DR GAPEN—No, no

CHAIRMAN—Do I understand you to refer to the opinion that experts are called upon to give in court?

DR GAPEN—On that point you agree entirely with me I do not say that an opinion should not be entertained by the expert An opinion is entirely proper, but an "opinion on the case" in law is a technical expression, if the expert states what his opinion is about the case, then he puts himself in the position of the jury

CHAIRMAN—As I understand it, the expert or witness will testify as to facts that come within his knowledge, in an examination of an individual, and he gives his opinion on the facts which he has studied himself, or his medical opinion on the facts which are stated in a hypothetical question or in some other way, he gives no opinion upon responsibility, for instance, in a case of insanity He does not assume the function of the court or the jury, but he gives an opinion upon the facts he has learned in investigation, and an opinion upon a hypothetical question, that is he gives an expert opinion upon it and it seems to me perhaps the doctor and I are agreed upon that matter

I fully agree with him in regard to teaching medical jurisprudence in our institutions, and I think with Dr Kiernan that the true solution of this problem like many others must be in the advance of education, and every other method of attempted improvement in these matters seems to me will fail As to the medical witness acting as counsel, I believe that very often properly and usefully, he acts as adviser to the attorney on the side that he happens to be retained for As Dr Kiernan said it is a common practice, and I do not see any objection to it, for the witness and the lawyer to go carefully over the case in order to see whether or not the witness will testify If he finds in going over the case that he does not agree with the gentleman who wishes to call him he refuses to testify, and in the same spirit he can, if he does agree, assist in the preparation of the case I agree with him, however, in reference to the injurious influence on the case which the appearance and particularly the manner in which a medical man sometimes appears in court assisting counsel I have had some experience in that and I have seen others in this position I avoid it wherever possible Lawyers sometimes insist on being assisted in the examination of witnesses My own experience teaches me that with the jury particularly, and I have no doubt with the judge in many cases, this often acts against the case very much and it would be a much better plan in the vast majority of cases for the witness to have nothing to do with the counsel in court except upon the witness stand I do not see anything morally wrong or legally improper in his giving assistance if he gives it in the proper spirit Now as to courts excluding experts I think it would be a very difficult matter in many cases for courts to say, and in many cases it would be very easy, but I remember only once in many trials seeing the court exclude a medical witness as not being competent to testify That was in a case of a man in Philadelphia who certainly was incompetent and who testified in a well known case there that he had made three examinations of the person who was on trial, a woman, and the district attorney in cross examination asked him what these three examinations were that he had made, whereupon he calmly stated that he had made a digital examination, a general examination and a speculum examination at the same time of the patient This man was ruled out

DR J E EMERSON—I think that the doctor has stated some of the difficulties in the way of successful expert evidence but, as it seems to me, aside from the ignorance of lawyers of medicine, a great deal is due to the personal character of the witness, his inability to express in terse brief language exactly what he means, so that he says a little more or a little less than he should, and, at the same time, his fearfulness of admitting ignorance is a great drawback to him In my observation and that of several of my friends who have been on the stand and who are well qualified as physicians to treat such cases, when they appear on the stand make very poor experts, simply from a hesitation to admit ignorance and from inability to express concisely just what they mean In regard to one point, of the witness acting as counsel, perhaps I misapprehend exactly the point, but it has been my observation that in many instances questions can be suggested to the lawyer by the expert witness which bring out the real merits of the case and which can not be brought out or will not be brought out in any other way It may be said that that is not acting as counsel, but simply to suggest questions I have a case in mind where a witness who went on the stand was asked by the opposing counsel if he was assisting counsel, he said, no, but he was requested by the lawyer to suggest questions to bring out the real merits and true facts of the case I can recall a case where the expert suggested such questions, where the questions all hung on whether the patient was epileptic or not, whether the homicide was committed during an attack of epilepsy or not The questions put by the medical expert through the lawyer essentially decided the whole case on its merits As regards experts giving an opinion in the case, while I know it is a legal maxim that legal experts should not be allowed to give an opinion in a case, yet I have in mind two cases that occurred in the courts in Michigan where the judge permitted exactly that thing to be done The question was put, "Have you heard all the testimony in this case?" Answer, "Yes" Q "What is your opinion from this testimony as to the mental condition of this patient?" And he was allowed to answer the question At the same time the Supreme Court of Michigan has ruled that such questions must be put in the hypothetical form

Dr J G Kiernan—I merely wish to make one statement that may avoid some little discussion in regard to a question that I raised It is a matter of record that the French Psychological Association came within three votes of urging the adoption of the Anglo Saxon expert system in France and the same is true of the German Psychiatrical Association, although by not quite so close a vote We find decisions of courts varying as to what constitutes an expert, and we find also that various tests are applied by different courts in varying conditions and that frequently opposite results are met with

Dr William Thomas Bishop—One phase of the medical witness which has not been brought out is of great importance As a general thing the expert would take care of himself, if medical jurisprudence were taught more fully and in a better manner than at present For instance, in the case of an accident on a railroad, if the physician knew just exactly how to make the examination and how to get the information when he first saw the patient, that would be a matter of the most vital importance in cases of injury which may result in death, also in cases of altercation, of abortion, etc, if physicians were educated up to getting what would be legal testimony, that would be worth a great deal But there is one misfortune about the medical witness and that is he often puts himself out of the way to get on the witness stand, he thinks it a smart thing to put himself on exhibition Another smart thing that he often does is to put himself in a position to antagonize some other practitioner I have seen a good deal of that My father was a criminal lawyer and I was raised in his office, he wanted me to be a lawyer, but I did not care for it, yet I have had some chance to judge of that matter, and one of the great troubles is that these experts get on the witness stand and do not for a moment admit that they are mere citizens the same as other witnesses, but want to claim privileges, here they make a great mistake, they are imprudent and indiscreet in their replies to counsel on one side or the other Another thing is, they undertake to explain the lawyer's questions instead of making the lawyer explain the questions himself, undertake to answer two questions with one answer and they make a mistake, but in regard to experts, the principle that applies to medical men, civil engineers and everything else is so broad that we can not interfere with it, that is that the judge is the one who determines as to the qualification and the capacity of a person to testify on a hypothetical state of facts, there is almost a general rule to this effect and all questions that you are asked as an expert must be asked and answered on a hypothetic basis, not as a matter of fact That runs all through the law, but if the doctors were a little more careful in giving a well protected answer instead of a broad and vulnerable one, stating that such a thing is utterly impossible and all that sort of thing, they would not get themselves in half as much trouble as they do

The expert who gives the lawyers advice outside of the court room and who assists in the preparation of the case is all right, but sometimes he is decidedly offensive You will see him crawling all over counsel on the other side, and he discounts his usefulness before the jury and before the court He certainly is simply committing professional suicide I think that if the legal position that the medical man occupies in the court is recognized as no different from that of any witness, if that were impressed upon the medical profession more fully, it would save the medical expert from a hundred indiscretions All he has got to do when he sees that the lawyer is crammed for him on a certain point, is to switch off on another line That will break the lawyer up

Dr Clark Gapen—I notice that I have used unconsciously legal terms that are misunderstood by us as medical men, and I think an explanation of these terms will perhaps remove the necessity for some of the criticisms that have been offered For instance, I used the term "witness as counsel" I do not mean by that that the witness shall not consult freely and advise freely with counsel in respect to the case, but when I say "witness as counsel," I mean counsel in the court room The law does not understand anything else in speaking of counsel, except as counsel in the case in the court room You will constantly see medical experts and medical men sitting by lawyers and advising them, and virtually acting as counsel The lawyer is a mere parrot repeating the words the doctor has put into his mouth, and that is what I object to There should be the freest consultation, and the freest advisory relation between the expert and lawyer before the case and during the case for that matter, but there is no better way for a lawyer to commit professional suicide than to have the medical expert sit by actually as counsel in the case

In respect to the term, "opinion on the case," that is a legal phrase and has a very distinct meaning in the law A lawyer would not hesitate on that a moment An opinion is a very different thing from an "opinion on the case" Dr Emerson has very well illustrated that You can ask a medical man, stating the evidence that has been adduced, Do you think such symptoms as these indicate insanity? What is your opinion as to the mental condition of an individual who presents these symptoms, enumerating all the symptoms that have been presented, now you give your opinion with regard to that There is no objection, whatever, to giving an opinion in that case But when you say, Have you heard the evidence in this case, and what is your opinion as to whether the prisoner is sane or insane? That is just exactly what the court and jury are there for to determine, and every supreme court has reversed cases where questions like that have been asked instead of the proper hypothetical ones It is a direct invasion of the province of the jury It may be a little unusual to medical minds to make the discrimination, but there is from a legal point of view the widest discrimination between giving an opinion on that identical case and giving an expert opinion relative to the facts involved in that case lawyers to form their theory through the aid of a physician in a given case The physician forms a theory of a case on the facts stated by the lawyer, and the testimony agrees generally much more thoroughly with the theory so formed than with the hit-or-miss method usually employed That was the case with the medico-legal issues arising in the Cronin matter In that case the attorneys consulted a physician who never appeared in the case and who made up the minor theories on which the blood question and the other questions were afterwards proven, and every one of the questions drawn up by him were laid before the experts afterwards With regard to the proposed remedies by the courts, I would say that it seems to me that the true remedy has been suggested by Dr Gapen, namely, instruction in our colleges in the first place, that in criminal cases every circumstance tending to prove innocence must be taken into account, and furthermore everything must be construed in the light of innocence, and guilt proven beyond reasonable doubt We find every day, physicians considering certain cases as exceptional and therefore not taking them into account, but swearing positively to a certain set of facts to which there are exceptions On the other hand, the point should be brought out that the question is one of preponderance of evidence merely in civil cases, and instruction should be given in that line as well as in criminal cases and the distinction clearly shown True medical jurisprudence is really not taught in our colleges, but in the place of it the Gradgrind method is used of pouring in mere facts

THE CHAIRMAN—I think many of the reader's points are well taken, still I do not believe that some of his remedies are practical It is a frequently made suggestion, that the trouble with reference to expert testimony and the evils connected therewith, could be overcome by making the experts the advisers of the court The method suggested by Dr Gapen is one, others have been suggested, but in the main they are on the same principle It has been suggested to have official court experts A very considerable experience in medico-legal matters leads me to believe that this plan would not work any better than the present except, perhaps, occasionally, at least, I am doubtful of it, and I believe as Dr Kiernan has said, that probably in Europe they are finding it somewhat of a failure It would be impossible for court experts to give opinions in an open jury trial, for or against a man, without the party accused being allowed full opportunity for expert and every other sort of defense Otherwise, it would be taking away the rights of the individual, and simply would result after a time in most of the cases that the court expert would be submitted to the same sort of examination and cross examination as anybody else, and with this additional difficulty in many cases that the court expert would be a political or personal or some other sort of obnoxious appointment, nor would the difficulty be removed by allowing the judges to call in in special cases a court expert I do not see how we could get around the difficulty in this way, although it has often been suggested I think I understood the doctor to say that opinion should not be tolerated

DR GAPEN—I used the expression, "opinion on the case," and I used it technically, not in the ordinary sense

DR KIERNAN—I understood that you meant hypothetical opinion

DR GAPEN—No, no

CHAIRMAN—Do I understand you to refer to the opinion that experts are called upon to give in court?

DR GAPEN—On that point you agree entirely with me I do not say that an opinion should not be entertained by the expert An opinion is entirely proper, but an "opinion on the case" in law is a technical expression, if the expert states what his opinion is about the case, then he puts himself *in the position of the jury*

CHAIRMAN—As I understand it, the expert or witness will testify as to facts that come within his knowledge, in an examination of an individual, and he gives his opinion on the facts which he has studied himself, or his medical opinion on the facts which are stated in a hypothetical question or in some other way, he gives no opinion upon responsibility, for instance, in a case of insanity He does not assume the function of the court or the jury, but he gives an opinion upon the facts he has learned in investigation, and an opinion upon a hypothetical question, that is he gives an expert opinion upon it, and it seems to me perhaps the doctor and I are agreed upon that matter

I fully agree with him in regard to teaching medical jurisprudence in our institutions, and I think with Dr Kiernan that the true solution of this problem like many others must be in the advance of education, and every other method of attempted improvement in these matters seems to me will fail As to the medical witness acting as counsel, I believe that very often properly and usefully, he acts as adviser to the attorney on the side that he happens to be retained for As Dr Kiernan said it is a common practice, and I do not see any objection to it, for the witness and the lawyer to go carefully over the case in order to see whether or not the witness will testify If he finds in going over the case that he does not agree with the gentleman who wishes to call him he refuses to testify, and in the same spirit he can, if he does agree, assist in the preparation of the case I agree with him, however, in reference to the injurious influence on the case which the appearance and particularly the manner in which a medical man sometimes appears in court assisting counsel I have had some experience in that and I have seen others in this position I avoid it wherever possible Lawyers sometimes insist on being assisted in the examination of witnesses My own experience teaches me that with the jury particularly, and I have no doubt with the judge in many cases, this often acts against the case very much, and it would be a much better plan in the vast majority of cases for the witness to have nothing to do with the counsel in court except upon the witness stand I do not see anything morally wrong or legally improper in his giving assistance if he gives it in the proper spirit Now as to courts excluding experts I think it would be a very difficult matter in many cases for courts to say, and in many cases it would be very easy, but I remember only once in many trials seeing the court exclude a medical witness *as not being competent* to testify That was in a case of a man in Philadelphia who certainly was incompetent and who testified in a well known case there that he had made three examinations of the person who was on trial, a woman, and the district attorney in cross examination asked him what these three examinations were that he had made, whereupon he calmly stated that he had made a digital examination, a general examination and a speculum examination at the same time of the patient This man was ruled out

DR J E EMERSON—I think that the doctor has stated some of the difficulties in the way of successful expert evidence but, as it seems to me, aside from the ignorance of lawyers of medicine, a great deal is due to the personal character of the witness, his inability to express in terse brief language exactly what he means, so that he says a little more or a little less than he should, and, at the same time, his fearfulness of admitting ignorance is a great drawback to him In my observation and that of several of my friends who have been on the stand and who are well qualified as physicians to treat such cases, when they appear on the stand make very poor experts, simply from a hesitation to admit ignorance and from inability to express concisely just what they mean In regard to one point, of the witness acting as counsel, perhaps I misapprehend exactly the point, but it has been my observation that in many instances questions can be suggested to the lawyer by the expert witness which bring out the real merits of the case and which can not be brought out or will not be brought out in any other way It may be said that that is not acting as counsel, but simply to suggest questions I have a case in mind where a witness who went on the stand was asked by the opposing counsel if he was assisting counsel, he said, no, but he was requested by the lawyer to suggest questions to bring out the real merits and true facts of the case I can recall a case where the expert suggested such questions, where the questions all hung on whether the patient was epileptic or not, whether the homicide was committed during an attack of epilepsy or not The questions put by the medical expert through the lawyer essentially decided the whole case on its merits As regards experts giving an opinion in the case, while I know it is a legal maxim that legal experts should not be allowed to give an opinion in a case, yet I have in mind two cases that occurred in the courts in Michigan where the judge permitted exactly that thing to be done The question was put, "Have you heard all the testimony in this case?" Answer, 'Yes" Q "What is your opinion from this testimony as to the mental condition of this patient?" And he was allowed to answer the question At the same time the Supreme Court of Michigan has ruled that such questions must be put in the hypothetical form

Dr J G Kiernan—I merely wish to make one statement that may avoid some little discussion in regard to a question that I raised It is a matter of record that the French Psychological Association came within three votes of urging the adoption of the Anglo Saxon expert system in France and the same is true of the German Psychiatrical Association, although by not quite so close a vote We find decisions of courts varying as to what constitutes an expert, and we find also that various tests are applied by different courts in varying conditions and that frequently opposite results are met with

Dr William Thomas Bishop—One phase of the medical witness which has not been brought out is of great importance As a general thing the expert would take care of himself, if medical jurisprudence were taught more fully and in a better manner than at present For instance, in the case of an accident on a railroad, if the physician knew just exactly how to make the examination and how to get the information when he first saw the patient, that would be a matter of the most vital importance in cases of injury which may result in death, also in cases of altercation, of abortion, etc, if physicians were educated up to getting what would be legal testimony, that would be worth a great deal But there is one misfortune about the medical witness and that is he often puts himself out of the way to get on the witness stand, he thinks it a smart thing to put himself on exhibition Another smart thing that he often does is to put himself in a position to antagonize some other practitioner I have seen a good deal of that My father was a criminal lawyer and I was raised in his office, he wanted me to be a lawyer, but I did not care for it, yet I have had some chance to judge of that matter, and one of the great troubles is that these experts get on the witness stand and do not for a moment admit that they are mere citizens the same as other witnesses, but want to claim privileges, here they make a great mistake, they are imprudent and indiscreet in their replies to counsel on one side or the other Another thing is, they undertake to explain the lawyer's questions instead of making the lawyer explain the questions himself, undertake to answer two questions with one answer and they make a mistake, but in regard to experts, the principle that applies to medical men, civil engineers and everything else is so broad that we can not interfere with it, that is that the judge is the one who determines as to the qualification and the capacity of a person to testify on a hypothetical state of facts, there is almost a general rule to this effect and all questions that you are asked as an expert must be asked and answered on a hypothetic basis, not as a matter of fact That runs all through the law, but if the doctors were a little more careful in giving a well protected answer instead of a broad and vulnerable one, stating that such a thing is utterly impossible and all that sort of thing, they would not get themselves in half as much trouble as they do

Dr Clark Gapen—I notice that I have used unconsciously legal terms that are misunderstood by us as medical men, and I think an explanation of these terms will perhaps remove the necessity for some of the criticisms that have been offered For instance, I used the term "witness as counsel" I do not mean by that that the witness shall not consult freely and advise freely with counsel in respect to the case, but when I say "witness as counsel," I mean counsel in the court room The law does not understand anything else in speaking of counsel, except as counsel in the case in the court room You will constantly see medical experts and medical men sitting by lawyers and advising them, and virtually acting as counsel The lawyer is a mere parrot repeating the words the doctor has put into his mouth, and that is what I object to There should be the freest consultation, and the freest advisory relation between the expert and lawyer before the case and during the case for that matter, but there is no better way for a lawyer to commit professional suicide than to have the medical expert sit by actually as counsel in the case

In respect to the term, "opinion on the case," that is a legal phrase and has a very distinct meaning in the law A lawyer would not hesitate on that a moment An opinion is a very different thing from an "opinion on the case" Dr Emerson has very well illustrated that You can ask a medical man, stating the evidence that has been adduced, Do you think such symptoms as these indicate insanity? What is your opinion as to the mental condition of an individual who presents these symptoms, enumerating all the symptoms that have been presented, now you give your opinion with regard to that There is no objection, whatever, to giving an opinion in that case But when you say, Have you heard the evidence in this case, and what is your opinion as to whether the prisoner is sane or insane? That is just exactly what the court and jury are there for to determine, and every supreme court has reversed cases where questions like that have been asked instead of the proper hypothetical ones It is a direct invasion of the province of the jury It may be a little unusual to medical minds to make the discrimination, but there is from a legal point of view the widest discrimination between giving an opinion on that identical case and giving an expert opinion relative to the facts involved in that case

Now with reference to the calling of experts, I would not do away with the English system at all, but I think that experts should be called something in this way each side should hand in a list of experts that he wishes called and the court should select an equal number from that list after hearing evidence, if necessary, with regard to the qualifications of any of the men on the list The court can, as it were, stop the proceedings and make a side issue of it as to whether this physician is expert with reference to the particular question, and the court should do so I think the greatest trouble that arises is in bringing in men who know nothing about the particular subject involved and opposing them to men who are learned Why the jury is very likely to conclude that the ignorant man knows the most, because the learned man makes discriminations which are absolutely incomprehensible to them The test should always be experience, and that test is recognized by the law

---

PUERPERAL HEMORRHAGE

Read in the Section of Obstetrics and Diseases of Women at the Forty fourth Annual Meeting of the American Medical Association

BY JAS P KERR
PITTSBURGH, PA

The subject which I have the honor of bringing before you is one which demands as much consideration as any in the whole category of medicine or surgery, because it is one of the most frequent complications of labor, and if the means and remedies are not applied and administered speedily and effectually, death is sure to ensue

It is most apt to come on at a time when least expected, and if not properly treated to be rapidly fatal Practitioners in general are too apt to consider all cases of labor normal, and not make any preparations for this accident, which is likely to occur at any time, so it is our duty to impress upon them the necessity of careful preparation and of a thorough study of each individual case Obtain, if possible, the patient's family history, discover whether she is, or is not, of a family of bleeders, and how much blood she has lost during her regular menstrual periods If a multipara, ascertain whether she has had hemorrhage at her previous confinements, how many children she has borne, and the length of time between each conception I am aware of the fact, gentlemen that in a country so cosmopolitan as ours, the general practitioner (who is usually called upon to fight these battles single-handed in the dead hours of the night, when assistance is far away) occasionally does not have an opportunity to see his patient until summoned to her "lying-in" bedside, consequently we oftentimes know nothing of our cases until brought face to face with them

There is no class of cases which require more prompt action, cool and wise judgment, than that of puerperal hemorrhage The golden rule of surgery must be obeyed to the letter, that is—"do not let your patient bleed to death," and to prevent that requires, first, a preparation for it, and second, a prompt application of the means and remedies which you have provided Picture a case of puerperal hemorrhage The obstetrician is called, finds the mother on her "lying-in-bed" suffering the throes of a confinement, her heart is buoyed up by hopes and expectations that her agonies will soon be over, and that she will soon press to her bosom a living issue of her womb, such hopes and expectations can only be experienced by a woman on the "lying-in-bed" Finally the child is delivered, the mother is happy and her friends are rejoicing, when suddenly without a sign of warning the life-giving fluid begins to flow away in torrents, we hear the death-like gurgle, we see the bleached and anxious expression and the purple lips, we feel the clammy and velvety condition of the skin which always supervenes a great loss of blood Our patient is pulseless, very restless, pupils dilated, and to all appearances the "King of Terrors" is about to invade this home,—and instead of joy and pleasure, we will have tears and sorrowing This woman, who has children dependent upon her, who are dear to her, and to whom she is dear, is cut down in the full vigor of womanhood without one moment's notice The time to act is at hand, we have no time to call a consulting physician, we must act promptly to save the life of this mother and wife

Then do you wonder that we insist so much upon a thorough knowledge of this subject, when a patient's life is thrown in the balance so suddenly, and nothing can save her except the prompt and skillful action of her attending physician who, to act, must have a thorough knowledge of the subject and be able to meet all emergencies? To be able to remove the cause and to apply the means and remedies which will put a new life in that prostrate form, and restore the wife to her husband, the mother to her children, and bring joy and happiness back to that household is characteristic of a true trustworthy physician

The skillful and experienced obstetrician who considers the responsibility which devolves upon him, the implicit confidence placed in him by his patient and her friends, has in consideration all the complications which may befall her during her parturition, he also considers by what means he is to successfully combat these complications, should they arise, to save the life of his patient

The necessity of strict asepsis is apparent to every one in the lying-in chamber Always hope for a speedy termination with happy results, but be prepared for any emergency which may arise, who can tell when, after the delivery of the child, he may be compelled to introduce his hand into the uterus to control a fatal hemorrhage, and would it not be criminal, with our knowledge of asepsis, to carry septic material into that uterus, and endanger the life of our patient? It only requires a few minutes to render your hands, at least, practically aseptic

We believe if there was more attention given to aseptic midwifery, the mortality would be much lower This brings us to the consideration of a class of cases which we encounter occasionally during the walks of obstetric practice, which strike the heart of the accoucheur with alarm, because of the gravity of these cases in the hands of the most skillful obstetrician I refer to accidental hemorrhage This accident is caused by the premature detachment of a normally situated placenta, which may be either partial or complete It may occur at any time during pregnancy, but rarely until the later months, often not until labor has commenced When the blood makes its way between the decidua and the membranes appearing per vaginam, we then have a typical case of accidental hemorrhage, but the blood may be retained in the uterus, constituting internal or concealed hemorrhage In concealed hemorrhage the blood collects either in the cavity formed by the central detachment of the placenta or between the uterine wall and the membranes, or in the amniotic cavity, or free in the uterus, but retained by a completely obstructing presenting part Accidental hemorrhage is comparatively rare, especially the grave form The detachment of the placenta causing this complication is most frequently due to an injury, such as a blow on the abdomen, or a fall Emotion or over-exertion may start a separation of the placenta If that imperceptible uterine action that goes on just before labor sets in should be unusually violent it may cause a small vessel of the placenta to yield, and the effusion which would be the result would act as a foreign body and excite further uterine action, and a partial or complete separation of the placenta would be the legitimate result It may also be the result of some of the general diseases, such as typhoid fever, variola and scarlet fever, or of some of the local diseases, such as albuminuria, acute yellow atrophy of the liver, also degeneration, and disease of the placenta itself It is generally met with in women who have borne many children, and in rapid succession, and in those who are suffering from anemia or impaired health from any cause It is rarely if ever met with in the primipara I had the misfortune to see a woman die from this accident a few years ago I have stood by the bedside of many poor individuals, in all conditions and circumstances of life, and watched the last spark of life expire, but I have never had an experience so sad as this one If there is anything that will strike the responsive chord in the heart of man and set the strings of sympathy in tune, it is to stand by the bedside of a dying mother and see the human life ebbing away Mrs L, 37 years of age, the mother of six children, who was expecting to be confined at any time, a woman of good family history, she had not had any complications during her previous confinements, never had an abortion or miscarriage, a woman of fine physique, but whom I had never seen until summoned to her dying bedside On the morning of the accident she arose at the usual time, and expressed herself as feeling as well as she had at any time during her pregnancy I presume she had albuminuria, from the condition of her feet and limbs, and from the symptoms which I elicited from her husband I was called about 11 30 A M She had not had any pain, had not received an injury, the uterus was not greatly distended The accident was apparently without any cause except the possible albuminuria, and came on without any warning There was a sudden gush of blood which rendered the woman pulseless, in fact when I arrived she was completely collapsed and still bleeding I immediately lowered the head of the bed, injected ergot, brandy and ammonia hypodermically I tried to excite uterine contractions by external manipulations of the uterus which was soft and flabby Made an examination, found the os dilated, soft and patulous, so I delivered by podalic version, which was accomplished without any difficulty, carried ice into the uterus, vinegar, turpentine and hot water, continued my external manipulations but could not stimulate permanent contractions and retractions of the uterus Hemorrhage went on, and the woman died in about fifteen minutes after delivery The placenta came away with the child, and from the coagula which had formed upon it I should think it had been wholly detached. Hemorrhage was so severe in this case from the beginning, that death was unavoidable It was just about an hour from the time hemorrhage began until the woman was a corpse

Open hemorrhage is recognized without any difficulty, as the appearance of the blood is sufficient and makes the diagnosis Concealed hemorrhage is more difficult to diagnose The symptoms are obscure Pain is usually present, and severe in character Associated with it are the symptoms of acute anemia, and in severe cases even collapse, without any apparent cause The uterus is usually greatly distended Labor pains diminish or cease entirely This accident may be confounded with rupture of the uterus In rupture the uterus is smaller, and the fœtus may be felt in the abdominal cavity through the thin belly wall The presenting part recedes, if it is not wedged in the pelvis The rent may also be felt and sometimes prolapsed intestines

Placenta prævia is one of the causes of hemorrhage, but as it is a subject itself it would require too much time to discuss it in this paper Hemorrhage during or after the third stage of labor may be either primary or secondary If it occurs during or within twenty-four hours after the third stage of labor it is primary If at any time during the puerperal period thereafter, secondary It may come on immediately after the birth of the child, and before the expulsion of the placenta, or it may follow the delivery of the placenta Any circumstance, whether functional inactivity, organic defect, emotional disturbance or mechanical obstruction to a firm closure of the uterus, acts as a cause and invites hemorrhage The anatomical relation of the muscular fiber of the uterus to its vascular system is such that during tonic contractions and retractions of the uterus, the muscular fiber acts as a ligature to the arteries and sinuses which ramify its walls, and hemorrhage is impossible It is very important, in fact absolutely necessary, to be familiar with the cause or causes of this accident, because intelligent and skillful treatment is based upon the cause, and a successful termination of the case will depend upon one's ability to early recognize the cause and remove it Functional inactivity or uterine inertia, bears a casual relation to this complication The predisposing causes of uterine inertia are, hydramnios, twin pregnancies, constitutional weakness produced by some of the wasting diseases, insufficient food or bad hygienic environments, exhaustion from prolonged labor—any cause that so affects the constituents of the blood as to prevent the formation of thrombi, predisposes to hemorrhage, also, hemorrhage diathesis, rapid delivery and the employment of anæsthetics during parturition Hemorrhage during and after the third stage of labor is often caused by the retention within the uterus of the placenta, or parts of the placenta I do not think any obstetrician of to-day, skilled in the practice of his profession, with the gift from God of good common sense, would dare to leave the placenta as a whole in the uterus, although this practice at one time had its advocates, but it is not rare for parts of the placenta to be retained

The formation and retention of blood clots may also cause hemorrhage This is generally due to uterine relaxation, uterine displacements or the retention of some small pieces of the placenta around which the clot formed, which may be either the result of too forcible or premature efforts at expression or extraction, or abnormal placental adhesions, or some abnormality of the placenta, multiloba succenturia, etc., lacerations of the cervix uteri, which may extend so far as to sever the circular artery. Lacerations of the vagina, or of the perineum, or extreme soft parts, are sometimes the source of serious hemorrhage after firm contractions and retractions of the uterus, and a careful examination will reveal the true cause of the hemorrhage. These lacerations should be repaired at once, so it is necessary for an obstetrician to be a surgeon as well. Many previously healthy women are made invalids by not receiving proper attention from the attending physician.

Repair these lacerations immediately, and prevent the suffering which often accompanies them. Fibroid tumors sometimes cause hemorrhage by preventing firm contractions and retractions of the uterus. Varicose veins in and about the vulva are sometimes the source of hemorrhage. Carcinoma, either of the body of the uterus or cervix, may cause hemorrhage. Retarded involution, which is often due to some of the displacements, such as retroflexion, is the most frequent cause of secondary hemorrhage, although all the conditions which cause primary hemorrhage also cause secondary hemorrhage. We are glad to say that severe postpartum hemorrhage is generally a preventable accident by a skillful management of the third stage of labor. If every case were treated as a case of itself, and as though hemorrhage was impending, there would be very few accidents of this kind. The attention should be directed to securing tonic contractions and retractions of the uterus as a prophylactic. This is done by carefully following the uterus down with the hand when the child is expelled, also by making pressure over the fundus, and by external manipulations. If the uterus is soft and flabby, give some of the preparations of ergot, pref. ergotin, by hypodermic injection. Misrachi claims that caffein acts more readily than ergotin, especially if the patient has lost much blood.

If the patients are known to be bleeders, or to have had hemorrhage during previous confinements, they should be prepared for their parturition several weeks before it is expected to come on.

Dr. John M. Duff of Pittsburgh, is in the habit of giving such patients strychnia. He begins six weeks or two months before the expected time, administering $\frac{1}{60}$ to $\frac{1}{30}$ grains of the sulphate three times a day. Considering the physiological action of strychnia, we think this treatment rational and scientific. Bossi considers hydrastis canadensis a very useful remedy in the treatment of hemorrhage both during pregnancy and during and after parturition. He administers it to patients with a predisposition to flooding, and claims excellent results. In the treatment of accidental hemorrhage, we must strive to control the hemorrhage and also sustain the patient. If the os is dilated, it is good practice to deliver as soon as possible; if it is not, use the Barnes' dilators and proceed to deliver. Murray advocates plugging the vagina where the os is undilated. I do not think this good practice, because it will not prevent the hemorrhage, but will only prevent its escape from the vagina, and the woman may literally bleed to death in her own womb. When the uterus is empty, we have more control over it; it may then be packed with iodoform gauze, as recommended by Duhrssen. Hot water injected into the uterus acts very kindly sometimes. Ice introduced into the uterus, and turpentine or vinegar, often give very satisfactory results. If these fail we may resort to the application of styptics. Ergot should be administered either hypodermically or by the mouth. The patient must be sustained, so we resort to stimulants. Brandy, ammonia, ether, etc., should be administered hypodermically and by the mouth. Warmth should be applied. The patient's head should be lowered and if necessary the extremities may be bandaged from the distal end up. A successful termination of the case will depend on our ability to control the hemorrhage, and the recuperative powers of the woman. This treatment also applies to severe postpartum hemorrhage. If the hemorrhage after labor is due to retention within the organ of portions of the placenta or clots of blood, they should be removed at once.

Dirska's method of controlling postpartum hemorrhage is to press the fundus firmly with one hand, with the other remove all clots, and then introduce into the uterus and upper part of the vagina two or three small pieces of ice. The ice is left in place for a few minutes, and pressure kept up for a quarter of an hour longer. He believes this method to be extremely efficacious.

Kochs recommends a mode of treatment of postpartum hemorrhage, which is at least novel; that is to invert the uterus, and put an india rubber band around the neck of the inverted organ; after six hours the band is removed and the uterus replaced. If hemorrhage is due to a laceration of the cervix which severs the circular artery, the artery should be ligated and the laceration repaired; lacerations of the vagina, perineum and soft parts should be repaired if possible. Fibroid tumors, if they assume the shape of an intra-uterine polypus, should be removed by scissors, after ligature of their base. If they can not be removed, administer ergot, quinia, and apply the faradic current daily. When hemorrhage is due to carcinoma, plugging the vagina is good treatment. If the patient is suffering greatly from anemia, we can resort to transfusion of blood, or, which is just as beneficial, a 3 per cent. solution of common salt.

Dr. T. Ridgeway Barker of Philadelphia, took exception to the plan of treatment suggested for the control of puerperal hemorrhage. He was a firm believer in the methods mentioned a few years ago, until he had a severe case of postpartum hemorrhage which terminated in the death of the patient. He had learned from experience in this case that ice, hot water and ergot were entirely inefficient, and their use led to a waste of precious time. He recommends a tampon of antiseptic gauze. In slight hemorrhage the measures first mentioned would effect control. He thought the number of cases seen by the practitioner were in inverse ratio to his experience in midwifery.

Dr. E. P. Davis of Philadelphia, said if the uterus is held in one hand and tamponed with the other it is a physical impossibility for serious hemorrhage to occur. This is a comparatively modern procedure. In England they were again discussing compression of the abdominal aorta.

Dr. Morris of Wisconsin, had saved a case twenty years ago by compressing the abdominal aorta with the hand in the uterus, reinforced part of the time by the other hand pressing upon the uterus from without. Other cases were seen by him, and treated successfully in the same manner.

Dr William L Buechner of Youngstown, Ohio, finds that he is able to control cases of postpartum hemorrhage with hot water Formerly he resorted to cold water and ergot with unsatisfactory results Ergot judiciously administered in the second stage of labor controls hemorrhage, and he finds if he does not give it that clots form, and that later these clots give way and hemorrhage takes place

Dr E E Montgomery of Philadelphia, emphasized the advantage of using strychnia, not only prior to the delivery of women who are disposed to bleed, but subsequent to it with a view to arresting hemorrhage, to awaken the nerve centers and prevent the collapse that takes place by the loss of blood He said we have no drug at the present day so effective in its influence upon the heart's action and muscular coats of the vessels as that of strychnia He doubts the practical value of compression of the abdominal aorta, especially with the hand in the uterus, as part of the blood supply comes from the ovarian arteries, which arise high on the aorta

Dr Giles S Mitchell of Cincinnati, Ohio, laid stress upon the importance of prophylaxis of postpartum hemorrhage He believes that almost every case of postpartum hemorrhage can be prevented if the accoucheur pays proper attention to the third stage of labor He has had a tolerably large obstetric practice, and does not remember of ever seeing a case of postpartum hemorrhage He has seen one case of accidental hemorrhage from the premature detachment of the normally implanted placenta Fortunately the patient recovered

---

THE ROUTINE PRACTICE OF ADMINISTERING ERGOT AFTER THE THIRD STAGE OF LABOR

Read before the Section of Obstetrics and Diseases of Women, at the Forty fourth Annual Meeting of the American Medical Association

BY T RIDGWAY BARKER, M D

PHILADELPHIA, PA

While the routine administration of any drug, one must admit, can scarcely be considered an indication of the highest degree of scientific knowledge yet, as the practice of medicine is not, and never can become, an exact science, since the personal equation always contains an unknown quantity, *vital resistance*, I think we may, without violation of current practice, adopt with advantage such a procedure

The old and apt proverb that an ounce of prevention is worth a pound of cure applies so forcibly to the employment of ergot after the termination of labor, in order to secure firm uterine muscular contractions and render them tonic, that this course would seem to be not only justifiable but actually indicated

Were it possible to prognosticate with any measure of certainty that Mrs A will suffer from uterine inertia with resultant hemorrhage, while Mrs B will not, then the opponents of this method would have some grounds on which to base their antagonism, but unfortunately for them, this foretelling the course of events has no foundation in fact and rests largely upon assumption, often not even reinforced by experience

I think I may declare, without fear of contradiction, that the occurrence of postpartum hemorrhage is due principally to a lack of correlation between uterine muscular contraction and coagulability of the blood, and while the latter, as I pointed out in a paper read before the Philadelphia Obstetrical Society in February, 1893, can readily be ascertained by noticing the tendency to clot formation by the blood escaping from the birth canal during the early stages of parturition, the other factor, (muscular contraction), must remain in doubt, since uterine exhaustion is liable to occur when least expected The realization of the above facts is absolutely necessary in order that one may follow out the arguments and results offered for consideration

Those who take exception to the routine practice of administering ergot, do not hesitate to say that it is suitable in most, if not all, cases of threatened postpartum hemorrhage, or where the uterus fails to contract promptly after the completion of the third stage of labor

This is undoubtedly sound reasoning, so far as it goes, but those on the affirmative side of the question say that it is not far enough

As I have endeavored to show, one can not tell when uterine inertia will occur, it may be within five minutes of the delivery of the fetus or it may be five hours Therefore, under such circumstances it is necessary in order to avoid this dangerous complication, that one resort to precautionary measures in every case 'Tis true, every woman who is confined, if properly attended does not suffer from postpartum hemorrhage, nor does the woman who is so afflicted necessarily die from its effects, yet it is too great a risk to run when nothing is to be gained thereby but rather a loss sustained, as I shall strive to prove

It has been said by some, who have given this method of administration a trial, that it "is neither necessary, expedient or devoid of danger" Further objection is offered that its routine use is liable to increase the parturient's discomfort by subjecting her to more severe and frequently recurring after pains

This is, in a measure, in accord with my observations, but I look upon after pains as synonymous with uterine contractions and while for the first few hours the discomfort as alluded to, is somewhat increased, I hold that this is more than balanced by the advantages which accrue from the immediate expulsion of all clots and dèbris from the uterine cavity, the more perfect and permanent closure of the uterine sinuses and the reduction in size of the placental site It is further claimed that there is danger in its administration from the fact that it may convert a simple hemorrhage into a concealed one and thereby increase the risk of sepsis Now just how it is possible for ergot to be guilty of such a thing I fail to comprehend

If the statement is based on the assumption that the drug is capable of causing complete stenosis of the cervical canal, I would ask for proof of a single case where such a condition could be so ascribed

In the first place, the effect of ergot is expended upon the whole layer of circular muscular fibers of the uterus, and not solely upon those in the immediate vicinity of the cervix

Besides the stimulating influence is not limited even to this layer but causes the longitudinal fibers, though to a less degree, to contract also Some have asserted that they noticed a rise in temperature follow the routine employment of this ecbolic

Such, however, has not been my experience, on the contrary,I have found the reverse to be the case, which I credit, not to any antipyretic effect inherent in the medicament, but to the more perfect retraction and depletion of the uterine vessels

That there exists great diversity of susceptibility to the action of ergot none will deny, but the variability would appear to be due in no slight degree to the strength of the preparation, and the time and method of administration

The above are some of the more general objections offered in evidence against this practice and yet, I can not but think they are more imaginary than real, since the routine method is being so generally adopted by some of the greatest clinicians and teachers in this country and Europe

Busey of Washington, D C, writing on the conduct of labor in "Hirst's System of Obstetrics," says "The routine administration of ergot at this stage of labor (after delivery of the placenta) is approved and practiced by many, if not a majority, of the most experienced and successful obstetricians, because it secures firm and persistent contraction of the uterus, lessens the danger of postpartum hemorrhage, protects in some measure the patient from septic complications, and promotes involution, whilst the dangers, if any, of producing hour-glass contraction of the uterus are too remote for consideration "

I therefore feel emboldened, when supported by such an authority and the results of my own personal experience, to declare myself in favor of this routine method, since by such means hemorrhage and its accompanying dangers are wellnigh impossible By the employment of ergot, in suitable doses, we place a trusty servant on guard to watch the uterus and see that it performs its duty, and should it be unequal to the task imposed upon it then this agent is at hand ready to lend assistance

Through its activity the uterus is reduced in size thereby lessening its encroachment upon the contents of the true and false pelvis Moreover, we can not fail to realize that by the closer crowding together and more perfect rearrangement of the muscular fibers the sinuses are practically obliterated, the thrombi smaller and the congestion of the organ relieved

Were the beneficial effects of ergot limited to the reduction in size of the placental site alone, it might well be considered a boon, for of all points within the cavity of the uterus this is the most vulnerable for the entrance of septic material since it is devoid of a protecting layer of epithelium

In this respect differing from the other portions of the cavity which recent researches go to prove is lined by an embryonic layer of epithelium which, while not attaining its full development until some weeks after separation of the decidua, yet serves a useful purpose as a protective against the entrance of pathogenic organisms

Accepting and appreciating this fact, one can not fail to realize the importance of reducing this denuded area to the minimum Though, as has been stated, the immediate discomfort of the parturient may be somewhat increased for a few hours, yet the subsequent annoyance from after pains is avoided, since the uterine cavity on the completion of labor is freed of all clots and dèbris which by their presence tend to excite muscular contractions

As to the danger attending the routine administration of ergot, I can not but think it is largely visionary, at least I have yet to meet with a single case though practicing this method for over two years, in which, in appropriate doses it has been productive of baneful effects, nor so far as I know, has any proof to the contrary been presented

Some of my opponents may claim that it is bad practice to interfere with nature when she is doing her work properly, and at first it would seem so, but when we consider that it is not *interference* but *assistance* that we render, the whole aspect of the case changes, and what appeared to be meddlesome midwifery proves really to be a judicious application of a scientific agent in the furtherance of a physiological process

The method of administration has, I believe, more to do with the rate of absorption and the degree of activity than is generally supposed Though at first I prescribed ergot in the form of fluid extract by the mouth in half drachm to drachm doses, I have of late discarded it, preferring one-quarter of a grain tablet triturates of ergotin, since their ingestion is free from the bad taste and stomachic irritation which always accompanies the fluid preparations

With regard to the hypodermic administration of ergot, I would say, that I have employed it in a considerable number of cases and found it to act promptly and efficiently, yet as the needle gives pain and its use is often objected to by the patient, without offering any additional benefit, I now but rarely have occasion to resort to the subcutaneous method

Where one has, however, to deal with a patient in a state of extreme exhaustion or collapse associated with or due to hemorrhage, this agent can not be relied upon since for its activity is required a more or less responsive nervous system This fact must be borne in mind, lest one postpone other and more efficient artificial measures for the control of hemorrhage until too late, when the rescue of the parturient becomes impossible

As to the oft discussed and disputed point that ergot assists and hastens involution, I wish to place myself on the affirmative side, believing as I must from clinical experience that it does facilitate fatty degeneration of the uterine muscular fibrillæ through its indirect influence upon the uterine blood vessels

It has been stated by my opponents that in the routine practice of administering ergot one can not know how large a dose to prescribe, my rule has been to order one quarter grain of ergotin in tablet triturate form, to be taken immediately after delivery of the placenta, and this dose to be doubled and repeated every half hour for the control of any excessive bleeding

In this way, I believe I have avoided the ingestion of any amount of the drug in excess of actual requirements The dose I am in the habit of employing may be said to be very minute, but I care not for its minuteness if it only does what is demanded of it

The object desired is not to drive nature to her work but to assist her should she fail One may very properly ask, how do you know that a dose of the size mentioned does benefit the parturient or even stimulate uterine contractions? To which I would reply, from the fact that shortly after its administration, uterine contractions are more frequent, lasting and complete, and by the prompt expulsion of all dèbris

In recommending the routine employment of this ecbolic it is not to be supposed that other measures are to be overlooked or neglected for the prevention of postpartum hemorrhage, just as much care should be exercised during every stage of the labor as under other circumstances The administration of ergot is not intended to correct bad and injudicious midwifery practice, but to aid and facilitate in the perfect restoration of the parturient to a physiological non-pregnant condition

To summarize, then, the advantages derived from the routine employment of ergot after labor, one I think, is justified in stating that, first, it insures the woman against possible uterine relaxation, second, it causes a reduction in the size of the uterus, which consequently encroaches less upon the pelvic viscera, third, the vessels in the uterine muscular walls are depleted and the force of the blood current reduced, fourth, it secures permanent closure of the uterine sinuses and allows the formation of firm clots at the mouths of the lacerated vessels, fifth, it reduces the area of the denuded placental site thereby lessening the danger of the entrance of septic matter into the circulation, sixth, it markedly diminishes the size of the uterine cavity with the resultant expulsion of all dèbris, seventh, it shortens the duration of after pains and renders the occurrence of fermentative changes within the cavity impossible, eighth, it hastens and facilitates the physiological processes incident to involution, ninth, the tablet triturate form of administration is to be preferred since it is rarely attended with nausea or vomiting, tenth, that it never does any harm in suitable doses and is always productive of good

Quite the contrary, I believe to be the case, and have so placed myself on record, when ergot is prescribed during any of the three stages of labor It is then a dangerous remedy and one likely to do far greater injury than any fancied good

For the above valid reasons I have adopted the routine practice of administering ergot after the third stage of labor and would recommend the same to those engaged in obstetric work as a valuable conservative measure

Dr Joseph Eastman of Indianapolis, Ind, said we must not forget that it is the law of all organs in the human body to have a period of life and a period of rest He objects to the routine use of ergot, because it substitutes tonic (unnatural) for clonic (natural) uterine contractions He is confident that he has seen cases of subinvolution of the uterus produced by the too persistent use of ergot He has seen cases where strychnia replaced ergot without interference with the normal clonic contructions of the uterus He has on previous occasions said, when speaking of the prevention of subinvolution of the uterus, that the use of ergot should be restricted to the third stage of labor He has gone even further and said that its use should be restricted to the satchel and not used at all, but this he thought was too extreme

Dr J A Murphy of Willkesbarre, Pa, finds that in cases where ergot fails to secure uterine contraction, mistletoe acts well

Dr John M Duff (the chairman), of Pittsburg, Pa, said he read a paper on the same subject last year in which he took an opposite view and argued against the routine use of ergot He thinks the routine practice of administering ergot after the third stage of labor is unscientific He administers it where he thinks it is indicated, and the obstetrician who is scientific and careful in his work will nearly always be able to tell in what cases it is indicated Those who have not tried strychnia in connection with cases in which they are afraid of hemorrhage, or in which there are severe after pains, will be agreeably surprised with the beneficial effects of it instead of ergot Nature should not be forced when she is doing her work normally

Dr C S Bacon of Chicago, said he had ceased the routine practice of administering ergot In several patients who were nursing children, he finds that its use has a perceptible effect in drying of the milk secretion, and his attention was called to the possible effect of it in the same way given immediately after labor Another objection was the uncertainty of its preparation

Dr Barker, in closing, said he had no doubt that if ergot were administered immediately after labor in the manner spoken of (large doses), it would give rise to the conditions named

THE ABUSE OF EMMET'S OPERATION FOR LACERATION OF THE CERVIX

Read in the Section of Obstetrics and Diseases of Women at the Forty-fourth Annual Meeting of the American Medical Association

BY E C DUDLEY, M D

CHICAGO

Emmet first operated for laceration of the cervix uteri in 1862 His published statement on the operation appeared in 1869 He published an elaborate paper on the subject in 1874,[1] and another in 1877[2] These papers were the outcome of many years' practical observation, not only of the operation itself, but of its relation to numerous pathological conditions, some of which the operation might cure, and others of which the abuse of the operation might cause

The original literature was characterized by conservatism, by completeness, by deliberation, it warranted, and subsequent results have justified, the prophesy of Marion-Sims, who said "We can't modify the operation, we can't change it, we can't improve, for it is perfect, perfect in its method, and perfect in its results Like all new operations it is likely to be abused, but the time will soon come when it will assume its place in the foremost rank of useful improvements" Notwithstanding the clearness with which the indications and contra indications, and the technique were defined, the operation, although no longer new, is often so badly executed as to be followed by most disappointing and sometimes by injurious results

We pass by with simple mention the abuse of the operation in cases unsuited to it, including those in which the laceration is slight, and not associated with uterine catarrh, cervical cystic degeneration, cervical erosion, cervical eversion We also exclude a large class of unfortunate cases, in which trachelorrhaphy is too often performed regardless of other and more important lesions, especially lesion of the uterine appendages and other peri-uterine structures.

The present discussion is confined to those failures following trachelorrhaphy, which are consequent upon faults connected with the execution of the operation itself, faults which often necessitate even the splitting apart of the united flaps, and doing the operation over again

The most common faults in the execution of trachelorrhaphy may be indicated as follows The operation may fail or do harm,

1 Because the operator has disregarded the presence of endometritis

2 Because the os externum has been closed so

---

[1] American Journal of Obstetrics, Nov, 1874

[2] American Practitioner, January, 1877

tightly as to obstruct the free outflow of uterine secretions and menstrual fluid.

3. Because the cicatricial plugs in the angles of the laceration have not been removed.

4. Because diseased cervical glands have been rolled into the cervical canal where they find expression either in the form of cervical catarrh, or of retention cysts.

Endometritis, which complicates so many cervical lacerations may pertain specially to the vascular structures or to the glandular elements of the uterine mucosa, and may consequently give rise to menstrual disorders or to uterine catarrh or to both. Among menstrual disorders menorrhagia is most common. Granular endometritis furnishes a positive indication for forcible dilatation, curettement, irrigation, and the application of strong carbolic acid and iodin, all of which should immediately precede closure of the cervix, except in aggravated cases when the curettement should be followed by thorough and repeated uterine tamponade of gauze after the method popularized by Dr. Polk. This tamponade would postpone the suturing until after the cure of the endometritis. Undoubtedly all this may be successfully done after the trachelorrhaphy, and in exceptional cases such a course might be wise, but it would reverse the more natural order of things.

First, cure the catarrh, then close the cervix to clinch the cure. But why close the cervix at all, if the catarrh is cured? It is a principle in physiology that if irritation be applied to the outlet of a duct leading from a glandular system, the secretion of the glands will thereby become exaggerated and may become pathological, hence the closure of the cervix is now indicated, because it removes such a source of irritation. Since following this line of ractice my results have so much improved that I ow hesitate to close the cervix without at least an ploratory curettement which often brings away a urprising amount either of granulation or of other material having a similar appearance, whose presence had not been suspected.

The evil consequences of closing the os externum to such an extent as to obstruct the free drainage of uterine secretions and menstrual fluid, are familiar to all observers. The pathological anatomy observed after such operation is the natural outcome of the stenosis which is often so extreme as to exclude the finest probe, and sometime amounts to total atresia. The secretions accumulate, distend the uterus, and sometimes even the Fallopian tubes, the secretions become decomposed, induce endometritis, metritis, salpingitis. These inflammations may even extend still further with most disastrous results, or may only keep up such a chronic irritation and congestion in the pelvis, as often to reduce the victim to a state of helpless invalidism. The rapid and complete relief which often follows the restoration of the normal caliber of the cervical canal and os externum, proves that the uterine canal is a natural drainage tube, the integrity of which is essential to health. In such cases, however, dilatation, curettement and uterine tamponade, or some other method may be further indicated to overcome the endometritis induced by the long retention of irritating secretions. The simple enlargement of the os externum, however, by incision is not permanent in its results, because the structures involved are cicatricial, and therefore prone to recontract. A plastic operation, by which mucous membrane is made to cover the cut surfaces is imperative. Schroeder's operation fulfills the indication perfectly.

We may omit any extended consideration of Emmet's injunction for the removal of all cicatricial tissue from the angles of the wound, although this important step in the operation is often disregarded. However, failure to remove it commonly results in failure of union, or imperfect union, a fortunate compromise for the patient, since the cicatrix is much less injurious with the laceration open, than with the laceration closed. When, unfortunately, union has taken place, the train of nervous symptoms which follows often necessitates the removal of the cicatricial plugs and the reclosure of the wound.

The common forms of disease of the cervical glands, i. e., the nabothian glands of which Tyler Smith estimates the number to be 10,000 in the virgin cervix, often demand special attention, in connection with the closure of the laceration. One form is characterized by the excessive outpouring of the familiar gelatinous white-of-egg-like secretion which acts as a tenacious plug in the cervical canal, very difficult to dislodge and usually present in enormous quantities in the upper portion of the vagina.

When the cervix has been closed, after the classical method of Emmet, this secretion is apt to continue unabated, nor is the usual preparatory treatment of topical applications effective for the removal of the disease. Indeed, any treatment in this form of disease which does not include the removal of the offending glands themselves, usually fails. Three methods of destroying the diseased glands are practiced.

1. Strong cauterization.
2. The free use of the sharp curette.
3. Excision.

The first two methods, i. e., cauterization and sharp curettement, are objectionable for the following reasons. First, the glands are so deeply seated in the mucosa that they always escape the caustic and the curette, unless these have been used with such hardihood as to produce excessive cicatrization and consequent stenosis, a condition quite difficult to remedy, even by plastic surgery. The excision of the glands on the other hand, and the closure of the cervix by the method of Schroeder, removes the disease and leaves the organs in a physiological state. After this operation, the cut surfaces can not cicatrize and contract, because covered by mucous membrane, this having been united by means of sutures to the intra-cervical mucous membrane. Schroeder has also found this operation the only effective means of curing cervical catarrh, not only in cases of cervical laceration, but also in cases in which there has been no laceration. In the latter class of cases he makes bi-lateral incisions, and proceeds with the operation the same as in cases of laceration.

The other form of glandular disease of the cervix, is that known as cystic degeneration. The ducts of the nabothian follicles having become obliterated by adhesive inflammation, the follicles become distended by their own secretions, and form retention cysts. The great increase in the size of the lacerated cervix, both before and after trachelorrhaphy is often due to the presence of cystic degeneration of these follicles, a pathological condition which often becomes much exaggerated when any of these diseased glands have been rolled into the cervical canal by trachelorrhaphy Oftentimes the cysts are present in great numbers, and of such enormous size as to lead to the suspicion that the consequent enlargement of the cervix may be from malignant disease Such a case has recently come under my observation, the patient having suffered from pronounced catalepsy since trachelorrhaphy was performed ten years ago An examination showed atresia at the os externum, excessive enlargement of the cervix, right ovary partly fixed, size of English walnut, left ovary fixed, slightly enlarged In order to ascertain the true condition of the interior of the cervix deep bi-lateral incisions were made, and the anterior and posterior lips were spread wide apart as they are in the most extensive laceration Much pent up secretion escaped from the uterine cavity, showing that the tight closure of the os externum had converted that cavity into a retention cyst, large numbers of cysts of the nabothian follicles appeared in the cervix, some miliary, others as large as small marbles In the excision of these cysts, almost all the mucous membrane of the cervix was removed The margin of the mucous membrane of the vaginal portion was then stitched with catgut sutures to the margin of the intra-cervical mucous membrane, both anteriorly and posteriorly, so as to fold the anterior and posterior lips ot the cervix upon themselves The lateral incisions were then closed with silkworm gut sutures, leaving the cervical canal permanently patulous This operation was practically that of Schroeder The perineum which was lightly lacerated was also closed The operation was performed about six months ago, and the patient although naturally neurotic, reports herself free from cataleptiform seizures, since her recovery from the operation This case, although striking, is only one of a large and increasing number of parallel cases, which illustrate possible evil results of bad surgery

In the preparatory treatment for trachelorrhaphy, experience has shown that the simple puncturing of cysts of the nabothian follicles by means of the spear pointed lance is inadequate, because the cysts are prone to be refilled They should either be destroyed by the cautery or excised The excision may be of the individual cysts, provided they are not too numerous, otherwise of the cervical mucosa

The evil results consequent upon the abuse of Emmet's operation, are frequently encountered, and a large part of the most necessary work, in connection with this operation, at the present time, consists of the conservative surgical procedures already outlined, the object of which is to undo work which has already been done If the abuse of the operation has done much harm, the misguided practitioner must bear the burden of his own fault, the operation must not be made to do so for him

LUNAR CAUSTIC—"You are worth a great deal more to people at some times than you are at others," said the comet sneeringly to the moon "That's why they call you the silver moon"

'Yes," replied the luminary, sadly, "it all comes of having to be taken at my phase value"—*Washington Star*

ORIGIN AND DEVELOPMENT OF THE GENITO-URINARY ORGANS IN WOMEN

Read in the Section of Obstetrics and Diseases of Women, at the Forty fourth Annual Meeting of the American Medical Association

BY F BYRON ROBINSON, B S, M D
PROFESSOR OF GYNECOLOGY IN CHICAGO POST GRADUATE MEDICAL SCHOOL, GYNECOLOGIST TO WOMAN S HOSPITAL, TO POST GRADUATE HOSPITAL, TO CHARITY HOSPITAL AND TO COLUMBIA DISPENSARY

The following remarks are based on original investigation in the human and in the lower animals, especially the pig The research embraces the examination of about 1,000 specimens of the genitals of the human and lower animals in various conditions and stages of development The investigation was carried to the bird family, and some interesting information was gained The development of the genito-urinary organs is one of the most fascinating of all studies, as the plans of evolution are most perfectly manifested in rapid succession As the organs develop, the subjects of hypertrophy and atrophy are seen in their most typical forms It is plain that in the embryo whole ages of evolutionary development take place in a few weeks, and that each of the distinct stages of the then distinct kidneys of mammals represent so many wide periods of animal life The economy and conservatism of nature is shown in its most beautiful manner—in the development of the genito-urinary organs by inducing organs and ducts to act first for kidneys and excretory organs, and finally for egg channels and gestation sacs The great capacity that organs have to modify themselves is a most instructive subject Every young physician should acquaint himself with the embryological development of the part of anatomy to which his future practice is likely to lead Embryology aids in comprehending the history of the growth of the genitals It enables one to comprehend the adult genital organs and gives frequently a clue to their pathology The so-called practical man may attempt to announce that the study of the development of the genitals is worthless because we can not change the course of deficient nature But to the scientific physician every stage of the development of the genito-urinary organs is an incentive for hopeful acquisitions that may avert deformities Malformation of the female genitals is simply nature caught in the act of wrong development In the widespread awakening of the present it is interesting to observe the family physician attempting to study the female genitals so that he may understand arrest of development, relics of atrophied organs and tumors from the same To be practical one must follow every stage of developmental structure Comparative anatomy sheds a flood of light on such work, and if one will carefully investigate the growth of the Wolffian body among the lower animals and man, the adult form of the genito-urinary organs will be relatively easy of comprehension About 1750, Dr Wolff of Berlin, Germany, began to announce the results of his studies on the genito urinary bodies The subject was so attractive that it drew to it some of the most brilliant names of literature who have enriched our libraries Mueller, Gartner, Rosenmuller, Waldeyer, Lankester, Raztke and Gegenbaur are but a few who have recorded their views on the Wolffian body The magnificent labors of Balfour, which read like a bewitching story, aided by the industrious Semper, have enabled us to distinguish the three grand divisions of the Wolffian body The best and most practical method of obtaining clear knowledge of the Wolffian body is to secure fetal pigs at the slaughter house The development of the Wolffian body is similar in all mammals, and pigs can be obtained from a day old up to birth

The Wolffian body is a complex, varying organ extending from diaphragm to cloaca or rectum on each side of the backbone It is oval or spindle-shaped In a small fetus the Wolffian body is the longest visceral organ and almost fills the abdominal cavity The dominating fetal viscus is the liver, which rapidly enlarges and induces the large and prominent abdomen of early vertebral life so characteristic of infants As the liver enlarges the Wolffian bodies decrease, perhaps in accord with the view that only one viscus can induce a high blood supply Under a good lens one can easily see the longitudinal ducts of the Wolffian body, and also the very numerous short ducts that enter at right angles to the longitudinal ones In typical specimens the naked eye detects all this and much more I will note the study of the Wolffian body in three stages, as it occurs in nature

1 The first stage includes the head kidney and its duct or ureter It is called the first kidney or pronephros, and its duct is the Mullerian duct

2 The second stage is known as the middle kidney and its duct It is called mesonephros, and its duct is known as the Wolffian duct

3 The third stage is called the third kidney with its duct It is the kidney of adult life and its duct is the ureter of adult life

1 The head kidney or pronephros will not be given much attention, as it is not functionally in the higher vertebrates It may only be active in the fetal life of man for a few hours But in lower animals, as fishes, it functionates a whole fetal and adult life It is the duct of the pronephros which concerns us as gynecologists, for it finally forms the vagina, uterus and Fallopian tube The duct of the head kidney is known as Muller's duct It is the Fallopian tube It first carried urine from the head kidney, but it finally carried eggs Nature is so conservative that she makes one organ do several functions In the female, then, the duct of the first kidney carried urine and then eggs, while in the male it first carried urine and finally atrophies to a small cyst found on the testicle and known as the hydatid of Morgagni Muller's duct of each side comes together in its posterior or lower two thirds, and the approximated walls fuse so that one tube results The fusion of the two ducts begins about the center of the middle third and proceeds both forward and backward This peculiar method of fusion explains why we may have a single uterus and a double vagina, or a single vagina and a double uterus The manner of fusion explains why we may have no uterus and a double or single vagina, or a uterus and no vagina

The upper third of the Mullerian duct develops into the Fallopian tube At the upper or anterior end of Muller's duct we can find, in some 15 to 20 per cent of cases, a small pedunculated cyst known as the hydatid of Morgagni This hydatid of Morgagni is perhaps the drawn out end of the upper mouth of the duct of Muller, or it may be a dilated uriniferous tubule of the pronephros In the chicken the duct of Muller forms a single channel from ovary to cloaca, and the funnel-shaped abdominal end of the Fallopian tube opens out on the ovary, i e, the rich hen's ovary sits right in the funneled mouth of the tube In the hen, Muller's duct is merely a channel to discharge eggs, and it hardens or calcifies them as they pass the irregularly lumened and tortuous duct The Muller ducts in a chicken do not coalesce, so that it acts in the hen as a vagina, uterus and Fallopian tube while it is only one channel But the hen's duct is lined with peculiar epithelium, and secretes albumen to coat the egg and calcium salts to protect it with a shell while the egg passes the duct, which lasts from one to three days A hen has, curiously, only one Muller's duct and one ovary—the left The right has atrophied Dr LucyWaite reported to me that while investigating the genitals of hens, she found remnants of the right atrophied Muller's duct in the form of dilated cysts near the cloaca I had also found similar vestigial remains of the atrophied right Mullerian duct in hens At first I thought it was unique in birds to have one Muller's duct atrophied and only one duct and ovary functionating but on further investigation it was found that several of the lower species of animals had the same non-symmetry of ovary and Mullerian duct

The explanation of the bird's loss of the right ovary and ova duct is not yet given A very interesting subject was found in the varying upper or abdominal end of Muller's duct In the pig, Muller's duct ends in an enormously wide, fringed funnel. This large funnel opened into a spacious peritoneal pouch in which lies the pig's ovary In the ovulation of the sow the ova drop either, first, into this large peritoneal pouch and then into the funneled mouth of Muller's duct, or the ova drop directly into the mouth of the duct In either case when the sow ovulates it is hardly possible to lose any ova on account of the peritoneal pouch In animals with multiple births nature provides large means to secure rich supplies for reproduction through the peritoneal pouch and the peculiar ending of Muller's duct There is a peritoneal pouch in many animals —e g, cat, dog, mouse, pig—in which the fimbriated end of the Fallopian tube opens The pouch is peculiar in each animal The peritoneal pouch decreases in animals up to man There is a small trace of a peritoneal pouch in woman which I have several times observed In all animals which I have investigated — sheep, dog, bird, cow, monkey, cat, man, there is a band of muscular or ligamentous structure which connects the fimbriated end of Muller's duct to the ovary Ascending in the scale of animal life, we have, first, the eggs simply drop out of a hole in the peritoneum, second, the peritoneal pouch exists, third, the mouth of the duct surrounds the ovary, as in birds, and finally, the ligamentum ovaricum persists as it is in monkey and man This little strip of muscular tissue which connects the mouth of Muller's duct to the ovary, shortens at menstruation or oestrus in all animals which I have examined In shortening it draws the mouth of the duct over the surface of the ovary, and that part of the ovarian surface which is ovulating may emit an ovum into the duct's mouth, but if the ovulating surface of the ovary lies outside of the mouth of the duct, the ovum may be lost In the cow as well as in the living woman, I have seen the wide mouth of the tube cemented to the ovary at its circumference by sticky mucus at menstruation The disappearance of the peritoneal pouch is in direct ratio to the disappearance of multiple births The typical sample of the peritoneal pouch at the end of the tube is the pig, which has a typical multiple birth In man the peritoneal pouch at the tubal end is least, and typical single births characterize the genus homo So that multiple and single births have some relation to the connection of the ovary to the mouth of the tube Muller's duct varies widely in its form and coalescence from the lower animals to man In some the two ducts do not coalesce, e g, birds, in some they coalesce but a little, e g, pig, cow and horse, in monkey and man we note that Muller's ducts coalesce for their lower two-thirds, i e, up to the Fallopian tube

One very valuable landmark to distinguish the uterus from the Fallopian tube was given to us by the immortal Virchow, that is, the round ligament The round ligament inserts itself in the duct of Muller at the junction of the uterus and Fallopian tube This means that all gestation is done in that part of Muller's duct posterior to or below the insertion of the round ligament Gestation is never done in the Fallopian tube of animals but in the horns of the uterus In a long search I have never known an authenticated case of tubal pregnancy in any animal below man Only, so far, has it been demonstrated that in woman tubal pregnancy occurs It would appear that a monkey was just as liable to tubal pregnancy as woman, from the structure and shape of the genitals, but no proof is yet recorded of tubal pregnancy in monkeys It would be interesting to note the various kinds of placenta that the Muller duct bears, but space forbids Suffice it to say that in the carnivora it is zonular, i e, it reaches all around the circumference of the duct or gestation sac in the form of a band In the herbivora the placenta is cotyledonous, i e the placenta rests on peculiar elevations of the gestation sac, shaped just like a mushroom on its stalk In the omnivorous, e g, the pig, the placenta is universal, i e, the choroidal membrane lies close against the mucous membrane of Muller's duct or the gestation sac In the quadrumana, as in monkey and man, the placenta is discoidal, i e, the part of chorionic membrane which nourishes the child lies on the mucous membrane in the form of a disc Muller's duct acquires various kinds of epithelium for a lining through the animal kingdom Where the ducts coalesce into vagina, uterus and Fallopian tube as in most higher vertebrates there are generally three kinds of epithelium membrane, as, e g, squamous for the vagina, glandular, columnar and ciliated for the uterus, and glandular, columnar and ciliated for the Fallopian tube But whether the duct coalesces or not, a certain part of its epithelial lining possesses peculiar properties of secretory powers In the bird the endothelium can secrete albumen and calcium salts In mammals it possesses the power to gestate In general, the ova may be viewed as a gland and the Muller's tube as its duct

2 The second stage of the Wolffian body is known as the middle kidney or mesonephros Its duct is known as the segmental duct or Wolffian duct The Wolffian duct and the Mullerian duct appear to me to be formed side by side Others assert that the segmental duct splits into two and thus is formed Muller's and the Wolffian duct The middle kidney or mesonephros and its duct probably functionates in the human fetus for six weeks In the pig the mesonephros functionates for about one-half its fetal life The middle kidney is the Wolffian body, proper, of vertebrates and it grows to a very large size It consists of an elongated body lying on each side of the vertebral column and reaching from diaphragm to rectum or cloaca One can easily see its long white duct running from its anterior end to its posterior end where it empties into the cloaca At right angles to this long duct which collects the urine, may be seen dozens of short tubes running into the long tube The chief portion of the Wolffian body is composed of these small coiled tubes The duct of the Wolffian body first carries urine, finally it atrophies in woman and the functionless remnant is known as Gartner's duct In the male it is transformed from a urinal duct to a channel to carry semen—the vas deferens Nature is conservative and utilizes already formed structures for additional higher functions Another feature is demonstrated, in that the urinary organs and genital organs are very intimate in their development and growth For example, the kidneys, ovaries, tubes, uterus and vagina arise from the same Wolffian body, then their food, lymph and nerve supply must be absolutely connected This principle of same nerve supply is applicable all through adult life and can be observed in many diseases, i e, a diseased ovary will affect the kidney or a diseased tube will disturb a kidney, by reflex action through its circle of nerves

The middle kidney or mesonephros, is of the highest interest to the gynecologist, because he has to deal with its vestigial remnants In woman, the whole middle kidney atrophies and its residue is known as the parovarium The remnants of this kidney were discovered by Dr Rosenmuller in 1801 The name parovarium was given to it by Dr Kobelt.

The mesonephros has shrunk to a trapezoid shaped organ and lies in mesosalpynx, i e, between the ovary and Fallopian tube Its pointed or smaller end runs to the lumen of the ovary It is composed of from eight to thirty tubules which run in a vertical direction These tubes are the uriniferous tubules of the mesonephros The tubes all pursue a course at right angles to a longitudinal tube known as Gartner's duct—the original ureter of the mesonephros The parovarium consists of three quite distinct parts (*a*) Gartner's duct This runs toward the uterus and in cows it runs near the mouth of the urethra, occasionally It no doubt represents Skene's tubes In the pig it is often many feet long and as large as a clay pipestem It has a large lumen in the pig, and I have frequently noted its atrophy at different intervals of its course, so that it represents beads strung on a string It shows also interrupted atrophy in the woman I have several times, in laparotomy, seen Gartner's duct dilated, once to the size of a child's head, and again I saw it dilated as large as an apple and the dilatations were strung along like beads Perhaps each dilatation represented the entrance of a uriniferous tube

b The chief remnant of the mesonephros is the vertical tubules of the parovarium, varying from five to thirty, visible to the naked eye To see the tubules one should hold the broad ligament up to the light These little tubules frequently dilate into cysts from the size of pin heads up to that of a child's head The tubules have a lumen lined with epithelium

c The third structure found in the remnant of the atrophic mesonephros is that known as Keibel's tubes

These are flask-shaped cysts or dilated parts of the uriniferous tubules situated external to the vertical tubules They frequently dilate and gradually acquire a long, thin pedicle The reason of the existence of these blind, flask-shaped tubes of Keibel must be the same as that for the hydatid of Morgagni

d Besides these three distinct structures, we find other relics lying in the broad ligament in the form of isolated cysts lying under the peritoneum But they have definite locations, e g , some are nearly always found at the upper border of the abdominal tubal sphincter Another place is along the tubal fimbriæ which connect the tube to the ovary They are all remnants of the mesonephros The parovarium has pathological cysts in it in 60 per cent of women according to my examinations I have performed laparotomy for parovarian cysts on women from 23 years up to 55 years Parovarian cysts do not develop before puberty, but they may develop as long as the woman lives after puberty The repeated rupture and refilling of parovarian cysts I have noted in my own patients No peritonitis occurred Sows have parovarian cystic degeneration One distinguishes a parovarian cyst from other cysts by its capacity of being peeled out of the broad ligament

3 The third stage of the genito-urinary bodies is known as the metonephros or adult kidney Its duct is the ureter The last kidney grows out just behind the mesonephros It starts as a little white body, and soon grows to a large size It has at first a spiral, crooked ureter, but as the bladder sinks down into the pelvis it straightens out The atrophy of the middle kidney and the hypertrophy of the third is a fascinating subject The blood stream is simply turned from the middle kidney to the last kidney, the one shrinks and the other grows The mesonephros simply pales from lessening blood, the metonephros reddens from excess of blood The mesonephros atrophies and the metonephros hypertrophies just by changing the blood current It may be observed that the duct or ureter of the first kidney persists in woman as Muller's duct, making the vagina, uterus and tube In the male it is the duct or ureter of the second kidney that acts as the vas deferens and epididymis to carry semen

By slitting open the abdomen of fetal pigs in various stages one can observe the beginning and course of the ovary It arises from the internal sides of the Wolffian bodies as a white spot as large as the head of a pin It is very vascular and very glandular It grows rapidly from a kind of large, luxuriant epithelium heaped up into a ridge named the genital ridge It is highly supplied by nerves and lymphatics It does not manifest sex until the tenth week in the human, and acts similar in the lower animals One can tell sex by the external genitals far sooner than by the testicle or ovary The ovary soon after the first three months begins to manifest its Grafian follicles, and it is always seen to be a cystic organ It sinks down in the pelvis and its artery, the ovarian, stretches out and becomes very long in the upright animals The ovarian arteries arise from the aorta, just below the renal, at the original site of the growth of the ovaries The Wolffian body is held to the diaphragm by a strong ligamentous cord which may be called the diaphragmatic ligament The body is also fastened to the groin by a process which is surrounded by peritoneum like the ferrule on a fork handle This process of tissue becomes the round ligament, while the peritoneum which surrounds it becomes the canal of Nuck This process of round ligament formation with Nuck's canal can be observed to perfection in the growth of fetal pigs It may be observed that adult kidneys of many animals are lobulated, the reason of this is that the adult kidney arose first in a lobular or separate form Each lobule was fed by an artery, so that even in adult animals some kidneys may be found with several arteries The kidney of a human fetus I have seen lobulated but it soon gets smooth In man, dogs, pig, sheep, etc , the kidney is smooth, and in 75 per cent it is fed by one renal artery Among some fifty human cadavers which I have carefully dissected I found that 25 per cent of the kidneys had two to five arteries In the cow, one can see the typical lobulated kidney which must originally have had an artery for each lobule The Wolffian body was originally generally drained by one vein and that would be the renal vein But the upright position of man and monkey has induced the ovary to fall into the pelvis and this lengthened the ovarian vein This ovarian vein originally opened into the main vein which would be the renal At present the left ovarian vein opens at right angles into the renal vein and it represents the original fetal life But the right ovarian vein opens at present into the vena cava just below the renal vein Now the explanation I offer for this is that the evolutionary changes have occurred on the right side by the upright position, as then the ovary would drag on the ovarian vein and finally it would be apt to enter lower down in the long vena cava, while the left side still retains its original fetal condition Gegenbaur explains it in another way by saying that the left ovarian vein is a remnant of the cardinal vein, considerable disease is due to the difficulty of venous return on the left side The supra-renal bodies, which develop with the genito-urinary, lie in the still unknown field of physiology They have some relation with the sympathetic nerve whose significance is yet unknown

1 Out of the Wolffian body arise the uterus, vagina and Fallopian tube The ovary, parovarium, kidney and supra-renal bodies come from the same source Hence they all have a physiological and anatomical connection

2 The genital and urinary organs arise from the same source and occasionally one is modified to act for the other

3 Since the whole of the genital and urinary organs have both an anatomical and physiological relation, the essential knowledge for the gynecologist will lie in the nerve connections, for disturbance in one organ will disturb the balance of all

4 Injury to the nerves in one organ will disturb the circulation and nutrition in the other by reflex action

5 The peritoneum and genitals are anatomically and physiologically connected Hence disturbance in one will disturb the others

6 The chief nerve supply of the genitals and urinary apparatus is sympathetic

7 The main pathology of the sympathetic nerve is reflex action which will disturb any distant or adjacent viscus

8 The irritation in pregnancy passes up the hypogastric plexus to the abdominal brain and is reflected out on the renal plexus, inducing albumen in the urine The aching back in menstruation is accounted

for by the close nervous connection of genitals and urinary organs The renal plexus and the lateral ganglionic chain is dragged on by the hypogastric plexus

9 The nephritis and albumen in the urine after vaginal hysterectomy is due to the wounding of the hypozotic plexus and ovarian plexus, and the irritation is reflected into the renal plexus disturbing the kidney The shock from abdominal and vaginal section is due to the damage inflicted on the sympathetic plexus, and is often manifest in kidney disturbance

10 The intimate anatomical and physiological connection of the *genitals, kidneys and peritoneum* by nerve, blood and lymph supply invites dangers to one by wounding the other The danger of disturbed balance is brought about by reflex action flashed from one organ to another through a reflex arc

11 The anterior and posterior columns of the vagina represent the remnants at the points where the ducts of Muller coalesce, producing thick columns of tissue

---

DOMESTIC CORRESPONDENCE

Does Tuberculin Scatter Tuberculosis?

AN OPEN LETTER TO DR HEATWOLE OF GOSHEN, IND , FROM DR DENISON OF DENVER, COL

Dear Doctor —The following are two extracts from the *Goshen Daily News* of Sept 4, which some one has kindly sent to me The cuttings are here transposed from their relative positions in the obituary notice, "A good citizen gone," so that the postmortem, which is what I wish to discuss, comes first

> "A POST MORTEM —This forenoon Dr Heatwole conducted an autopsy on the body of the late George N Thomas, assisted by Drs Bowser, Latta, Ash, Irwin Miller, Johnson and Whitmer It confirmed the diagnosis of the case, and revealed the fact that the Koch treatment had stopped the progress of the disease on the lungs, but had scattered it all over the glandular system, finally attacking the spine and brain which was the immediate cause of death
>
> ' The growth just under the knee proved to be a solid gland, five by seven inches, and had invaded the knee to such an extent as to entirely destroy the joint the ends of the bones at the knee joint having entirely disappeared
>
> "He had been a great sufferer for nearly three years, and especially so for the past few months, which he bore bravely and hopefully, although recovery was hopeless About seven years ago a growth like a tumor appeared on his leg just back of the knee caused by tuberculosis The growth increased gradually but not until about three years ago were his lungs affected Since that time he has traveled in climates which promised benefit, but improvement was only temporary While in Denver he took the Koch treatment and it apparently healed his lungs but the growth on his leg was constantly increasing in size until the leg became as large as his body and very painful A few days ago tubercular meningitis developed, becoming so severe on Saturday that he became unconscious that night, in which condition he remained until his death "

Prompted by a desire to do justice to a most useful remedy (tuberculin) I am persuaded to write you

For it has seemed to me that we ought to blame ourselves more and the remedy less, and then there would be hope of our becoming well acquainted with tuberculin and its modus operandi, as well as that of the disease it antagonizes, to use it intelligently and with good results The medical profession must be introspective and look to tuberculosis as well as to the composition of the remedy, for an explanation of the so called "failures" of tuberculin The delusion, which hinders a thorough understanding of the remedy, is that it inoculates with tuberculosis, or the above inference that it spreads the disease Whenever *insufficient diagnosis*, *unsuitable conditions* for a cure, and *excessive use* of tuberculin, such as obtained in the unfavorable results in the Johns Hopkins and the Pennsylvania hospitals,—whenever these conditions are behind the so called "failures" I feel like nailing the evidence where it belongs This is my reason for wishing to review this case of my former patient, (Nov 1892 to March 1893), to see if this dissemination of tuberculosis through the glandular system was subsequent to or followed the administration under my hands of Koch's tuberculin On this point it seems to me there are fairly three reasons why the stated conclusion of the autopsy is in error Of course I want to admit that this may be merely a *lapsus pennæ* of a newspaper reporter, but it expresses a popular prejudice and a false position taken by many physicians inexperienced with this new method of treatment, which position is not easy to combat with our insufficient knowledge of tuberculosis and tuberculin The three reasons are ,

1 The tumor in the popliteal space antedated the appearance of any lung lesion whatever by three years I deem it unnecessary to refer to the frequency with which tuberculosis originates in other parts before manifesting itself in the lungs Of course there may be a question raised as to the fact, but I am going to assume that the nature of this tumor, as stated in the account, was unique all the time from its beginning , i e , tuberculous, because under tuberculin treatment it grew hard and there was an effort to contract or shrink, and because the postmortem evidences showed that the most prolonged existence of tuberculosis was in the joint underneath the tumor I had my good friend Dr C Theodore Williams of London, when he was visiting us last November, see this patient When the doctor felt the tumor he exclaimed "Oh ! lymphadenoma, there is no question about it" All of which would go to show that tuberculosis was behind the lymphadenoma, and served to confirm in my own mind a theory I have had for some time, that *the bacillus of tubercle is not the beginning of tuberculosis* Instance our general inability to find the bacillus in glandular tumors known to be tuberculous by tuberculin reaction or otherwise, or in adenoid growths in the region of the third tonsil which I have known to be removed, as simply adenoid, from those who were steadily advancing in the tubercular process, as subsequent history proved

2 The implication of the glandular system antedated the use of tuberculin in this case, and may have been a resultant of la grippe two years previous I have known of other supposedly tuberculous subjects in whom the influenza seemed to center the tubercular poison in the glands of the neck In this case both the thyroid glands were becoming much enlarged, there were nodular glands above the clavicles and both breasts were tender and as large as a young maiden's

3 The reaction to tuberculin was not only in the affected lung, but in all these affected glands, especially in those above the clavicles, the breasts and in the tumor under the knee, showing that there was tubercular contamination there before tuberculin was given In the case of the tumor on the leg, the size of which was 7½ inches, measured lengthwise with the limb, and 10½ inches across the center, the effect of the treatment was a hardening of the soft mass and a restraint of its growth during the continuance of the tuberculin injections The pain caused there was a positive hindrance to the use of the larger doses of tuberculin This was the principal reason, probably, why Mr Thomas gave up the method at two different times although in all other respects the effect was quite favorable At one time he almost agreed to the proposition, which the autopsy now proves would probably have been best, namely, to amputate the limb and continue the immunity producing effect of tuberculin It was with a view of settling this question that Mr Thomas wished to consult with Dr Senn, and I was glad to have him do so, but of course did not expect Dr Senn to take my view of an operation with his expressed opposition to the use of tuberculin

I think I have made out my case that in this instance the scattering to the glands had occurred before the tuberculin

These are flask-shaped cysts or dilated parts of the uriniferous tubules situated external to the vertical tubules They frequently dilate and gradually acquire a long, thin pedicle The reason of the existence of these blind, flask-shaped tubes of Keibel must be the same as that for the hydatid of Morgagni

d Besides these three distinct structures, we find other relics lying in the broad ligament in the form of isolated cysts lying under the peritoneum But they have definite locations, e g , some are nearly always found at the upper border of the abdominal tubal sphincter Another place is along the tubal fimbriæ which connect the tube to the ovary They are all remnants of the mesonephros The parovarium has pathological cysts in it in 60 per cent of women according to my examinations I have performed laparotomy for parovarian cysts on women from 23 years up to 55 years Parovarian cysts do not develop before puberty, but they may develop as long as the woman lives after puberty The repeated rupture and refilling of parovarian cysts I have noted in my own patients No peritonitis occurred Sows have parovarian cystic degeneration One distinguishes a parovarian cyst from other cysts by its capacity of being peeled out of the broad ligament

3 The third stage of the genito-urinary bodies is known as the metonephros or adult kidney Its duct is the ureter The last kidney grows out just behind the mesonephros It starts as a little white body, and soon grows to a large size It has at first a spiral, crooked ureter, but as the bladder sinks down into the pelvis it straightens out The atrophy of the middle kidney and the hypertrophy of the third is a fascinating subject The blood stream is simply turned from the middle kidney to the last kidney, the one shrinks and the other grows The mesonephros simply pales from lessening blood, the metonephros reddens from excess of blood The mesonephros atrophies and the metonephros hypertrophies just by changing the blood current It may be observed that the duct or ureter of the first kidney persists in woman as Muller's duct, making the vagina, uterus and tube In the male it is the duct or ureter of the second kidney that acts as the vas deferens and epididymis to carry semen

By slitting open the abdomen of fetal pigs in various stages one can observe the beginning and course of the ovary It arises from the internal sides of the Wolffian bodies as a white spot as large as the head of a pin It is very vascular and very glandular It grows rapidly from a kind of large, luxuriant epithelium heaped up into a ridge named the genital ridge It is highly supplied by nerves and lymphatics It does not manifest sex until the tenth week in the human, and acts similar in the lower animals One can tell sex by the external genitals far sooner than by the testicle or ovary The ovary soon after the first three months begins to manifest its Grafian follicles, and it is always seen to be a cystic organ It sinks down in the pelvis and its artery, the ovarian, stretches out and becomes very long in the upright animals The ovarian arteries arise from the aorta, just below the renal, at the original site of the growth of the ovaries The Wolffian body is held to the diaphragm by a strong ligamentous cord which may be called the diaphragmatic ligament The body is also fastened to the groin by a process which is surrounded by peritoneum like the ferrule on a fork handle This process of tissue becomes the round ligament, while the peritoneum which surrounds it becomes the canal of Nuck This process of round ligament formation with Nuck's canal can be observed to perfection in the growth of fetal pigs It may be observed that adult kidneys of many animals are lobulated, the reason of this is that the adult kidney arose first in a lobular or separate form Each lobule was fed by an artery, so that even in adult animals some kidneys may be found with several arteries The kidney of a human fetus I have seen lobulated but it soon gets smooth In man, dogs, pig, sheep, etc , the kidney is smooth, and in 75 per cent it is fed by one renal artery Among some fifty human cadavers which I have carefully dissected I found that 25 per cent of the kidneys had two to five arteries In the cow, one can see the typical lobulated kidney which must originally have had an artery for each lobule The Wolffian body was originally generally drained by one vein and that would be the renal vein But the upright position of man and monkey has induced the ovary to fall into the pelvis and this lengthened the ovarian vein This ovarian vein originally opened into the main vein which would be the renal At present the left ovarian vein opens at right angles into the renal vein and it represents the original fetal life But the right ovarian vein opens at present into the vena cava just below the renal vein Now the explanation I offer for this is that the evolutionary changes have occurred on the right side by the upright position, as then the ovary would drag on the ovarian vein and finally it would be apt to enter lower down in the long vena cava, while the left side still retains its original fetal condition Gegenbaur explains it in another way by saying that the left ovarian vein is a remnant of the cardinal vein, considerable disease is due to the difficulty of venous return on the left side The supra-renal bodies, which develop with the genito-urinary, lie in the still unknown field of physiology They have some relation with the sympathetic nerve whose significance is yet unknown

1 Out of the Wolffian body arise the uterus, vagina and Fallopian tube The ovary, parovarium, kidney and supra-renal bodies come from the same source Hence they all have a physiological and anatomical connection

2 The genital and urinary organs arise from the same source and occasionally one is modified to act for the other

3 Since the whole of the genital and urinary organs have both an anatomical and physiological relation, the essential knowledge for the gynecologist will lie in the nerve connections, for disturbance in one organ will disturb the balance of all

4 Injury to the nerves in one organ will disturb the circulation and nutrition in the other by reflex action

5 The peritoneum and genitals are anatomically and physiologically connected Hence disturbance in one will disturb the others

6 The chief nerve supply of the genitals and urinary apparatus is sympathetic

7 The main pathology of the sympathetic nerve is reflex action which will disturb any distant or adjacent viscus

8 The irritation in pregnancy passes up the hypogastric plexus to the abdominal brain and is reflected out on the renal plexus, inducing albumen in the urine The aching back in menstruation is accounted

for by the close nervous connection of genitals and urinary organs The renal plexus and the lateral ganglionic chain is dragged on by the hypogastric plexus

9 The nephritis and albumen in the urine after vaginal hysterectomy is due to the wounding of the hypozotic plexus and ovarian plexus, and the irritation is reflected into the renal plexus disturbing the kidney The shock from abdominal and vaginal section is due to the damage inflicted on the sympathetic plexus, and is often manifest in kidney disturbance

10 The intimate anatomical and physiological connection of the *genitals, kidneys and peritoneum* by nerve, blood and lymph supply invites dangers to one by wounding the other The danger of disturbed balance is brought about by reflex action flashed from one organ to another through a reflex arc

11 The anterior and posterior columns of the vagina represent the remnants at the points where the ducts of Muller coalesce, producing thick columns of tissue

DOMESTIC CORRESPONDENCE

Does Tuberculin Scatter Tuberculosis?

AN OPEN LETTER TO DR HEATWOLE OF GOSHEN, IND , FROM DR DENISON OF DENVER, COL

Dear Doctor —The following are two extracts from the *Goshen Daily News* of Sept 4, which some one has kindly sent to me The cuttings are here transposed from their relative positions in the obituary notice, "A good citizen gone," so that the postmortem, which is what I wish to discuss, comes first

> "A POST MORTEM —This forenoon Dr Heatwole conducted an autopsy on the body of the late George N Thomas, assisted by Drs Bowser, Latta, Ash, Irwin, Miller, Johnson and Whitmer It confirmed the diagnosis of the case, and revealed the fact that the Koch treatment had stopped the progress of the disease on the lungs, but had scattered it all over the glandular system, finally attacking the spine and brain which was the immediate cause of death
>
> ' The growth just under the knee proved to be a solid gland, five by seven inches, and had invaded the knee to such an extent as to entirely destroy the joint the ends of the bones at the knee joint having entirely disappeared
>
> ' He had been a great sufferer for nearly three years, and especially so for the past few months, which he bore bravely and hopefully, although recovery was hopeless About seven years ago a growth like a tumor appeared on his leg just back of the knee caused by tuberculosis The growth increased gradually but not until about three years ago were his lungs affected Since that time he has traveled in climates which promised benefit, but improvement was only temporary While in Denver he took the Koch treatment and it apparently healed his lungs but the growth on his leg was constantly increasing in size until the leg became as large as his body and very painful A few days ago tubercular meningitis developed, becoming so severe on Saturday that he became unconscious that night, in which condition he remained until his death "

Prompted by a desire to do justice to a most useful remedy (tuberculin) I am persuaded to write you

For it has seemed to me that we ought to blame ourselves more and the remedy less, and then there would be hope of our becoming well acquainted with tuberculin and its modus operandi, as well as that of the disease it antagonizes, to use it intelligently and with good results The medical profession must be introspective and look to tuberculosis as well as to the composition of the remedy, for an explanation of the so called "failures" of tuberculin The delusion, which hinders a thorough understanding of the remedy, is that it inoculates with tuberculosis, or the above inference that it spreads the disease Whenever *insufficient diagnosis, unsuitable conditions* for a cure, and *excessive use* of tuberculin, such as obtained in the unfavorable results in the Johns Hopkins and the Pennsylvania hospitals,—whenever these conditions are behind the so called "failures" I feel like nailing the evidence where it belongs This is my reason for wishing to review this case of my former patient, (Nov 1892 to March 1893), to see if this dissemination of tuberculosis through the glandular system was subsequent to or followed the administration under my hands of Koch's tuberculin. On this point it seems to me there are fairly three reasons why the stated conclusion of the autopsy is in error Of course I want to admit that this may be merely a *lapsus pennæ* of a newspaper reporter, but it expresses a popular prejudice and a false position taken by many physicians inexperienced with this new method of treatment, which position is not easy to combat with our insufficient knowledge of tuberculosis and tuberculin The three reasons are ,

1 The tumor in the popliteal space antedated the appearance of any lung lesion whatever by three years I deem it unnecessary to refer to the frequency with which tuberculosis originates in other parts before manifesting itself in the lungs Of course there may be a question raised as to the fact, but I am going to assume that the nature of this tumor, as stated in the account, was unique all the time from its beginning, i e , tuberculous, because under tuberculin treatment it grew hard and there was an effort to contract or shrink, and because the postmortem evidences showed that the most prolonged existence of tuberculosis was in the joint underneath the tumor I had my good friend Dr C Theodore Williams of London, when he was visiting us last November, see this patient When the doctor felt the tumor he exclaimed "Oh ! lymphadenoma, there is no question about it " All of which would go to show that tuberculosis was behind the lymphadenoma, and served to confirm in my own mind a theory I have had for some time, that *the bacillus of tubercle is not the beginning of tuberculosis* Instance our general inability to find the bacillus in glandular tumors known to be tuberculous by tuberculin reaction or otherwise, or in adenoid growths in the region of the third tonsil which I have known to be removed, as simply adenoid, from those who were steadily advancing in the tubercular process, as subsequent history proved

2 The implication of the glandular system antedated the use of tuberculin in this case, and may have been a resultant of la grippe two years previous I have known of other supposedly tuberculous subjects in whom the influenza seemed to center the tubercular poison in the glands of the neck In this case both the thyroid glands were becoming much enlarged, there were nodular glands above the clavicles and both breasts were tender and as large as a young maiden's

3 The reaction to tuberculin was not only in the affected lung, but in all these affected glands, especially in those above the clavicles, the breasts and in the tumor under the knee, showing that there was tubercular contamination there before tuberculin was given In the case of the tumor on the leg, the size of which was 7½ inches, measured lengthwise with the limb, and 10½ inches across the center, the effect of the treatment was a hardening of the soft mass and a restraint of its growth during the continuance of the tuberculin injections The pain caused there was a positive hindrance to the use of the larger doses of tuberculin This was the principal reason, probably, why Mr Thomas gave up the method at two different times although in all other respects the effect was quite favorable At one time he almost agreed to the proposition, which the autopsy now proves would probably have been best, namely, to amputate the limb and continue the immunity producing effect of tuberculin It was with a view of settling this question that Mr Thomas wished to consult with Dr Senn, and I was glad to have him do so, but of course did not expect Dr Senn to take my view of an operation with his expressed opposition to the use of tuberculin

I think I have made out my case that in this instance the scattering to the glands had occurred before the tuberculin treatment was commenced and therefore was not due to it

That the final breakup, which must come, of course, sooner or later, was through the climax in tubercular meningitis is not strange I have now seen nine cases where the lungs were more or less completely healed through climatic influence, and death came through tubercular meningitis, usually from some intercurrent exciting cause It is, perhaps, pertinent to this particular affection of a joint for me to add that the young lady who Mr Thomas will remember as coming to my office on crutches for tuberculin treatment, and who had had tubercular arthritis of both knee joints for about four years, so that she had not stepped on the floor for over two years, has so fully recovered that I hear of her in her Vermont home as walking to church even without a cane Other cases of glandular tubercular implication have done excellently well, but there is, of course, a necessity for a more persistent or prolonged course than when the glands are not affected, the same as with partially healed pulmonary cavities where the multiplication of tubercular bacilli is with difficulty prevented While I am on this subject of tuberculin, I wish to say here what I could not, when I wrote my paper a year and a half ago for the American Climatological Association, namely that I have found Kleb's Tuberculocidin to answer excellently well in some feverish, erethric and sensitive cases where the real tuberculin (Koch's) would be inadmissible It is about one-fortieth the strength of the latter and does not increase a previously existing fever as tuberculin does However, the descriptions of its preparation and directions for its use are criticised as not being very lucid I very much wish that some of our bacteriologists this side the Atlantic ocean would take hold of this matter and reasonably supply us with these useful preparations

Finally, Doctor, I wish to remind you that frequently disseminated tuberculosis, as several cases I have diagnosed by tuberculin injections would seem to show, does not manifest itself in the lungs until the system is profoundly under the influence of the disease Furthermore, the final dissemination to the glands, in most cases of tuberculosis ending in death, comes at that period when the individual vitality is lowered to the point where resistance is exhausted, and where it is unreasonable to conclude that any other agency scattered the tuberculosis to the glandular system Very respectfully yours,

CHARLES DENISON

Has Practiced Abroad, but does not Specify His College

To the Editor —As the JOURNAL is looked to abroad as the exponent of American medicine, is it not likely that foreign medical boards will think that our Association approves of inferior medical colleges, when some of the very worst in the United States are given constant advertising space in the JOURNAL, thus injuring all American diplomas? Having practiced for some years in a foreign country I know with what contempt the "Yankee" M D is held, and this is because of the shameful ignorance shown by most of our graduates who have left our shores seeking fame or fortune in foreign climes, and who, of course, were always from inferior colleges

Yours, etc ,

D C NEWMAN

Can Get All the Cerebrin He Wants

To the Editor —Dr G Archie Stockwell can get all the "cerebrin" made in May, 1893, he wants, and for nothing, provided he will, under the eyes of three physicians to be selected by the editor of the JOURNAL, repeat with it the experiments on himself which he alleges in the *Medical News* of Aug 26, he performed Satisfactory evidence will be given that the "cerebrin" is of the date mentioned

WILLIAM A HAMMOND

To Whom Credit is Due

To the Editor —In your issue of Sept 16, there appears a letter from Dr Hinde, in which he calls attention to a certain oversight in giving due credit for our joint report of a case "Periodically Recurring Oculo-motor Paralysis" The facts are that Dr Hinde first saw the case and credit is due him alone for having differentiated this rare condition The case was shown me and I subsequently made an exhaustive study of the bibliography which, with the notes of the case formed the first paper published in the *Medical Record* No one regrets more than myself the fact that Dr Hinde has not been credited with this interesting observation, and I now wish distinctly to state that I had nothing to do with the case further than that I examined it, studied the literature, and wrote the first paper

Dr Hinde says in closing that credit ought to be divided in this case I think not, as it belongs exclusively to him

Very truly yours,

HAROLD N MOYER

NECROLOGY

Dr W C Wardlaw, died in Atlanta, September 2 For many years Dr Wardlaw has been practicing his profession in Augusta, Ga He had been elected Dean of the Dental College at Atlanta, and had just moved to that city, preparatory to assuming his new duties

He was prepared for the South Carolina College, in the village school where he was graduated, and afterwards attended lectures at the Charleston Medical College, intending to make medicine his profession, but, the war coming on he was obliged to suspend his studies, and enlisted in the services of his State, and it was here that Dr Wardlaw displayed that endurance, courage and heroism which endeared him to his men, and called forth the commendation of his Commanding General and the compliments of his Colonel

He was desperately wounded during the war, and from the effects of that wound it was said he never recovered, and that his death was attributable to it

Returning from the war shattered in health and empty in purse he determined to adopt dentistry as his profession, a calling to which his great ingenuity and former knowledge of surgery well fitted him After practicing his profession in Abbeville for several years, subsequent to the war, he moved to Angusta, and rapidly rose to prominence in his profession

Dr Charles L Dayton, one of Buffalo's best known physicians, died Sept 7, at his residence on Dearborn street after an illness of about ten days Typhoid enteritis is said to have been the immediate cause of death Dr Dayton was born in the town of Eden, New York He was graduated from the Buffalo Medical college in 1854 and established a successful practice at Black Rock which continued for nearly forty years

He was a brother of Dr Lewis P Dayton, ex-mayor of Buffalo, and many years ago he held the position of health physician of Buffalo He was a member of the Erie County Medical society, and also of the Occidental lodge of Masons

Dr Robert Ferguson, at Anderson, Indiana, Sept 10

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

SUBSCRIPTION PRICE, INCLUDING POSTAGE
PER ANNUM, IN ADVANCE $5 00
SINGLE COPIES 10 CENTS
Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No 68 WABASH AVE, CHICAGO, ILLINOIS
All members of the Association should send their Annual Dues to the Treasurer, RICHARD J DUNGLISON, M D, Lock Box 1271, Philadelphia, Pa

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION

This is obtainable at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association All that is necessary is for the applicant to write to the Treasurer of the Association, Dr Richard J Dunglison Lock Box 1274, Philadelphia Pa, sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society with five dollars for annual dues and subscription for THE JOURNAL Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly

SATURDAY, SEPTEMBER 23, 1893

THE NEED OF ORGANIZATION

The daily press are just now engaged in a crusade against our colleague, MR ERNEST HART, for his outspoken speeches against telepathy, theosophy, hypnotism Keeleyism and homeopathy It seems that whenever there is opportunity, the press generally take the side opposed to the professional view This fact can not well be controverted But it is scarcely fair to the press to accuse them, as MR HART has, of having a moneyed interest in charlatanry The truth is that the real fault lies with the medical profession itself The average State medical society scarcely contains ten per centum of the profession within the State The average legislator therefore hastily concludes that the medical society is the profession—that there are none outside except the irregulars, and he very naturally infers that the irregulars constitute a large proportion of the medical practitioners He thereupon passes laws giving representation on State boards of health and other bodies to all descriptions of medical heretics and charlatans If the medical profession will only organize by union with their local, State and National medical associations, they will show their real strength No politician can afford to ignore organizations controlling so many votes, and there can be no doubt but much of the official misrepresentation to which the profession has been subjected will cease when the eligible members of the profession unite

The effect upon the press of thorough organization would be no less striking than its effect upon the political class, and a timely intimation that the united medical profession had, by a duly constituted committee, investigated the subject of "———ism" and found it wanting, would put a brake on quack notoriety, except, perhaps, that embodied in paid advertisements, and even these may be suppressed later through the gradual enlightenment of public opinion A united medical profession can mold public opinion on all professional topics

These are among the reasons why organization is so desirable and so necessary That the medical men of this country are beginning to act upon this conviction, we have evidence in the steady increase of membership in the AMERICAN MEDICAL ASSOCIATION Forty-one new members were added last week and there were ten restorations to membership in the same week The increase in the membership, including those who joined at Milwaukee, for the three months ended August 31, is 351 We added this week one hundred and twenty copies to our mail list We sincerely hope that the good work may be actively pushed by every member of the ASSOCIATION, so long as any of the one hundred thousand physicians remain out of the fold Blank applications can always be furnished by the JOURNAL, and will be sent to any member who desires them in such quantities as he may wish

CHARAKA-SAMHITA

The oldest of the Hindu medical books known to be complete, the Charaka, is undergoing translation at the hands of the learned DR AVINASH CHANDRA KAVIRATNA The sixth fasciculus of the Charaka lies upon our table The difficulty about ancient Hindu literature is the absence of dates, the Hindu chronology being utterly fabulous

The laws of hygiene and of diet, however, have been studied by the Hindus from the earliest times The Ayur Veda, the "science of life," is the oldest of their books, and as was customary in all oriental mythology its origin is said to be divine, having been prepared by BRAHMA in the Satyar-yuga

WISE, in "History of Medicine Among the Asiatics," gives the following list of authors

AUTHOR'S NAME	NAME OF THE WORK	
	FOUND	SUPPOSED IRRECOVERABLE
Atrya	Atri Sangita	
Agnivesa Charaka	Charaka	
Bhila		Bhila Tantra
Jatukarna		Jatukarna Tantra
Parásara		Parásara Sangita
Harita	Harita Sangitá	
Kárpari		Kárpari Tantra
Dwonwantaree Susruta	Susruta	

These works are all compiled on the plan of the Ayur Veda

The Charaka is a system of oral instructions delivered by AGNIVEÇA (or AGNIBESA,) and commented upon by CHARAKA The work is compared to that of HIPPOCRATES, and WISE asserts as a strong probability that much of the Hippocratic knowledge was derived from the Hindu preexisting work

The origin of modern concours may be traced *in* the oriental mythology, which narrates that *once* upon a time, when the world was young, *the sages* were brought together to read their works on *medicine* for purposes of comparison and adoption *That of* the sage AGNIBESA received such approbation *that* "with a voice which reached to Heaven" the assembled sages proclaimed their admiration

Years rolled by, and Charaka corrected and revised the work of Agnibesa which then became the exponent of Brahminical medical lore

The directions translated in the present fasciculus for the construction of a hospital are interesting

> In the first place a mansion must be constructed under the supervision of an engineer well-conversant with the science of building mansions and houses It should be spacious and roomy The element of strength should not be wanting in it Every part of it should not be exposed to strong winds or breezes One portion at least should be open to the currents of wind [1]
>
> It should be such that one may move or walk through it with ease It should not be exposed to smoke, or the sun, or dust, or injurious sound and touch and taste and form and scent It should be furnished with staircases, with pestles and mortars, privies, accommodation for belting, and cook-rooms [2]
>
> After this, should be secured a body of attendants of good behaviour, distinguished for purity or cleanliness of habits, attached to the person for whose service they are engaged, possessed of cleverness and skill, endued with kindness, skilled in every kind of service that a patient may require, endued with general cleverness, competent to cook food and curries, clever in bathing or washing a patient, well conversant in rubbing or pressing the limbs,[2] or raising the patient or assisting him in walking or moving about, well-skilled in making or cleaning beds, competent to pound drugs, or ready, patient and skilful in waiting upon one that is ailing, and never unwilling to do any act that they may be commanded (by the physician or the patient) to do A number of men should also be secured that are skilled in vocal and instrumental music, in hymning encomiums and eulogies, conversant with and skilled in reciting verses and pleasant discourses and narratives and stories and legendary histories, clever in reading the face and understanding what is wanted by the patient, approved and liked by him upon whom they are to wait, fully conversant with all the requirements of time and place, and possessed of such politeness as to become agreeable companions The mansion should also be stored with an adequate supply of Lāva (*a*), Kapinjala (*b*), Caca (*c*), Harina (*d*), Ena (*e*), Kālapuchchhaka (*f*), Mrigamātrika (*g*) and Urabhra (*h*) [3]
>
> A cow also should be kept, yielding copious milk, of a quiet disposition, healthy, having all her calves living,[4] well tended with food and drink and kept in a fold that is properly cleaned So also should be kept little vessels or cups, larger vessels for washing the hands and face, water vessels or jars, small jars or pitchers, dishes, metallic or earthen jars, caldrons or pans, larger and smaller jars,[5] vessels called *kundas*, hollow vessels for covering articles, wooden or metallic ladles, mats, covers of cloth or blankets, vessels for boiling oils and ghee, churning rods, deerskins and sheepskins, rags, cloths made of cotton and wool, strings and chords, beds and seats, vessels called *Bhringáras* full of water and flatter vessels for holding spittle and evacuations, all placed ready for use, good beds placed upon bedsteads and overlaid with white sheets and containing pillows, for use when sleep is needed, beds and carpets for lying down or sitting upon, articles necessary for the operations of *Sneha*, *Sweda*, *Aiyanga* plasters, fomentation, rubbing vomiting, purging, application of oily or other kinds of enemata, errhines, urination and passing of stools, well washed mullers and flat stones that are smooth and rough and neither smooth nor rough, and diverse kinds of instruments, domestic and surgical Smoking tubes, enemas, and enemas of a special kind called *uttaravastikas* brushes and brooms, balances and weights, measuring vessels and baskets Ghee, oil, fat, marrow, honey, treacle, salt, fuel, water, honey-wines, sour gruels of different varieties, different kinds of wines, whey, butter-milk, sour gruel of paddy or rice, and the different varieties of animal urine, should also be kept ready

We have not space to give any more of this most learned and ancient production of the Hindus, at this time, but we can here only express our admiration, alike for the scholarship of Dr Avinash Kaviratna, and the industry which has produced the work, and as well the liberality of the publisher

CANNED VEGETABLES

The Chemical Division of the United States Department of Agriculture has just issued another part of its Report on Foods and Food Adulterants, technically known as Bulletin No 13 The present issue, Part VIII, deals with canned vegetables, especially with regard to methods of preserving, the preservatives employed, the character of the vessels used and the food value and digestibility of the articles A few words concerning this report may be of use, inasmuch as owing to the publicity given to it, medical practitioners may be questioned as to their views on the subject Tin and lead were found, derived from the cans and solder, copper from salts of the metal used for "greening" the vegetables, zinc in some samples of French goods, and sulphurous and particularly salicylic acid, employed for their antiseptic properties Boric and benzoic acids, saccharin and hydronaphthol were not found in any of the samples examined Tin is the most common metallic contamination, being present in every can that has been put up for any length of time Tin poisoning from the use of canned goods is not often alleged, although Hehner and other experimenters have found stannous hydrate to exercise a marked poisonous action on guinea pigs and other small animals Lead is freely used by the packers both in the solder and in low grade tin plate, but there is little danger of lead poisoning by the use of canned goods, for tin precipitates lead from its solutions and lead is not attacked by acids in the presence of as much tin as is found in the tin plate used There is more danger of lead poisoning from the sheet lead tops of glass jars than from the solder or lead of the tin cans The quantity of copper needful for "greening" amounts to only a quarter of a grain per pound, but much more than this quantity was often found The temperature required to destroy spores in vegetables tends to disintegrate many of them and render them less attractive in appearance, hence the use of salicylic acid Doses of one-half to one and a half grains of this acid have been given and taken daily by experimenters for periods of many months without affecting the system in any notable way Nevertheless its action on the kidneys is recognized, and in exceptional cases of renal disease its continued ingestion in the quantity present in canned goods may be harmful In dyspeptic cases, also, the antiseptic may do harm by interfering with the normal action of the digestive ferments

---

[1] The meaning is that though protected against the breeze or strong winds one portion of the mansion should be exposed to the breeze —T

[2] Samvāhaka' is explained by the commentator as Hastapadādi sammarddaka —*T*

[3] *a* Perdix chinensis
b The francoline partridge
c The hare
d The common variety of the spotted deer
e The black antelope
f The black tailed deer
g A large species of deer fatter towards the abdominal and hinder parts
h Sheep

[4] If a cow loses a calf that is taken as an indication of ill health or of some disease —*T*

[5] These are all vessels of smaller or larger size for holding water They differ also in shapes

A trade journal criticises the report for conveying the impression that there is a widespread use of injurious antiseptics in injurious quantities, and points with emphasis to the fact that over one thousand million of cans are packed and consumed every year in this country alone and no well authenticated case of sickness has been traced to them, which could not with equal force be attributed to the use of similar articles not canned The chemists, however, do not intend to convey that impression nor to urge a prohibition of the use of copper salts and preservatives, but they claim the right on behalf of the people, of being informed by notice on the label of the can whether any ingredient foreign to the vegetable is present Packers should not be permitted to use these substances without notice plainly given of their presence and quantity, for the purchaser should be accorded the privilege of electing whether or not he will take the doses

AN APPEAL FOR PEACE AND TOLERANCE

The *Boston Medical and Surgical Journal*, August 24, gives prominent place to an article on "Sectarianism in Medicine" Four extra pages appear to have been added to that issue in order that the said article may be printed in its entirety The peculiarity of the article may be judged from the fact that the author thereof arrogates to himself and his party all the charity and good-will that lies in the possession of our fraternity, while applying to the standard bearers of rational medicine the most hateful of epithets, such as, "bigotry, intolerance, narrowness," also the adjectives, "pretentious and fraudulent" The writer would remodel all medical societies according to an "ideal" of his own conception, without the restraint of ironclad by-laws and codes of ethics, and without any wholesome knowledge whether any such societies have hitherto been tried and found wanting So far as our knowledge extends, the experiment has been tried once in this country, in the State of New York, but in no other country and no other State Ten years have gone by, and the organization which threw off the restraints of "bigotry and intolerance" remains about where it was when it started—less prominent, if anything can be judged of it from the outside, the assumption ten years ago, by its leaders, of all the better qualities of heart and mind has really done no harm and has converted nobody The old paths of rational medicine have not been destroyed, the ethically persuaded members of the profession are still intent upon their errands of mercy, and are ignorant of much that is said and written about their bigotry and narrowness of spirit The writer of the article mentioned above has our thanks for one paragraph, namely, that wherein he rejects the term "allopath" as applied to the rational branch of medical practice. He says "The impudence of those who would force medical men who do not believe in homeopathy as a general principle, and who refuse to place the slightest limitation upon their practice to accept the title, allopath, is colossal" The word "allopath," and others having the same etymological signification, should be uncompromisingly rejected by every member of the profession, not only as being non-descriptive, but, as conveying a false impression These terms are not used at the present time to the same extent as formerly, but we even now occasionally meet with them in situations where the audience has a right to expect a purer form of expression

In conclusion, let us remind the writer that the honorable sentiments of justice, fair play, and toleration are as certainly the characteristics of medical men as of any other body or class of men It is bad taste and poor diplomacy in one who bears a flag of truce and terms of capitulation to hurl abusive epithets at the heads of those who "hold the fort" Little efficacious work in the way of peace-making can be brought about in this manner

CLASSIFICATION OF CHEMICAL SALTS AND COMPOUNDS AS PREPARATIONS OF COAL TAR

The United States Circuit Court of Appeals affirmed May 17, 1893, the judgment of the Circuit Court, reversing the decision of the board of general appraisers in the cases of Roessler & Hasslacher Chemical Co and W J Matheson & Co, Limited, its decisions being now just reported in 56 *Federal Reporter*, pp 481, 482 It holds that the provisions of the tariff act of March 3, 1883, imposing a duty of 20 per cent on "all preparations of coal tar, not colors or dye," not specially provided for, applies to a product, the determining characteristic of which is something which it has received from coal tar, notwithstanding some of the constituents of coal tar have been eliminated, and other substances added, and that under this rule, napthionate of soda is dutiable as a preparation of coal tar, and not as a chemical salt, under the subsequent provision of the act, (22 Stat 494, Tariff Ind New, *par* 92) imposing a duty of 25 per cent "on all chemical compounds and salts," not specially provided for, while tolidine base and binitrotoluole are dutiable as preparations of coal tar, and not as chemical compounds, under the subsequent provision of the act

A GOOD BEGINNING —Dr Plummer, the chairman of the Committee of Arrangements at San Francisco, has begun his labors by sending in the names of nine new members by application This is one of the many evidences of the great movement now going on in building up the ASSOCIATION

PAN-AMERICAN EXCURSION

AT BOSTON

[From the Boston Herald]

The South Americans and all the other foreigners among the delegates of the Pan-American medical congress, recently held in Washington, who arrived in Boston Sept 12, had a gay time in their own way as the guests of Boston physicians

There are about sixty of the visiting physicians, and a good many of them are accompanied by their wives and families

Yesterday morning they visited the Massachusetts General Hospital, where they were carried from the Brunswick in three or four big transfer coaches

The Pan Americans looked like foreigners Most of them seemed not to understand more than the most commonly used English words and phrases, and Dr A Bustillo and Dr Julis Selva of the Harvard medical school, acted as official interpreters

The visitors went through the Massachusetts General Hospital under the escort of Supt Pratt Dr Pratt, in describing rooms or instruments or operations, spoke in English, and Mr Bustillo diffused his knowledge in the sweet toned Spanish tongue

The party were escorted to Boston by Dr Adams of Washington, and were met at the depot by Dr Selva and Dr Bustillo

Gen Ybarra met the delegation later to act as an escort Arthur P Cushing, Mexican consul, and his brother, Dr E W Cushing of Boston, were also at hand to do their part in entertaining

The visitors while here are the guests of the Massachusetts Medical Society, the committee of entertainment from which is composed of Dr J C White chairman, Dr H P Walcott, Dr S H Durgin, Dr A T Cabot, Dr E H Bradford, Dr J C Warren and Dr R H Fitz

After the party got a pretty fair idea of our hospital they were driven to the Harvard medical school They all gathered in the dean's room, on the first floor, where Dr J C White detailed the plan for inspection through Interpreter Bustillo

Two by two the Pan Americans went from the bacteriological exhibit room down stairs to the dissecting room on the top floor

Some found departments they liked, and made long stops, having everything explained

Shortly before 1 o'clock the ladies of the party arrived at the medical school They had been entertained by Gen Ybarra and Mr Cushing, the Mexican consul, and thoroughly enjoyed the drive about the city and suburbs

The ladies and children were mostly pronounced brunettes A few of them resembled the typical Brazilian maidens of the dark skinned, dark-haired types like the Misses Mendonca, daughters of the Brazilian minister in Washington during the last administration

At 1 o'clock all the delegates and their families sat down to lunch in the medical school

Wednesday, Sept 13, the program for the delegation was to visit the City Hospital from 9 30 to 12 30, and from 1 to 6, at the invitation of the Boston board of health, they visited the sanitary and quarantine stations in the harbor

In the morning the ladies were entertained by Dr E W Cushing at his private hospital in Roxbury, and visited with him the Woman's Charity Hospital Lunch was served at Dr Cushing's hospital, and then the ladies were taken by Dr Cushing to join the excursion down the harbor to the quarantine stations

The party was composed of the following

Dr V L Giles D M Hayti Dr Aug Corneau Hayti both relations of the dethroned King of Hayti Dr J E Monjaras professor of medical jurisprudence and general inspector of the Board of Health San Luis Potosi Mexico Dr Lagleyze, Buenos Ayres Argentine Republic Dr M Gutierrez, professor of obstetrics of the Medical School, Mexico City John Van Renssaeler Hoff major medical department United States Army Dr Angel Conteras professor of clinics Medical College, Pueblo Mexico Dr A M Fernandez y barra, assistant secretary general of the Pan American Congress New York P C Remondino editor of the *National Popular Review* Chicago Dr Manuel Carmona general director of the Medical College Mexico Dr Rogue Maconzet Mexico City Henry B Baker secretary State Board of Health, Lansing Dr E Liceaga president of the Board of Health, San Andres Mexico David Contreras, Mexico Dr G Vargus Paredes Bogota Colombia Dr J R Ycaza Mexico Ernest W Cushing editor of *Annals of Gynecology and Pædiatry* Boston Dr Enrique Lopez, Havana Cuba Dr Francisco Marin, Pueblo, Mexico Dr George C Ober Washington, D C Dr Alfredo Garces Popayan Colombia Dr Guan Mendieta, Buenos Ayres Argentine Republic Dr G Wythe Cooke, Washington, D C Dr George N Acker Washington D C Dr James G McShane, Baltimore Md John A Hopper, Washington D C Dr Lins E Ruiz Mexico City Dr Daniel Gutierrez Manezales Colombia Dr Juan J Ulloa San Jose, Costa Rica Dr Emilio, Echeverria Costa Rica Dr C H A Kleinschmidt, Washington D C Dr George H Rohé Catonsville, Md Dr G L Magruder Washington D C Mr De Pablo George E Ranning, Lansing Dr Antonio Jover Havana Cuba Dr Gregorio Mendizaval Mexico Dr J R Wolfe Glasgow, Scotland, Dr Ernest Hart, editor of the *British Medical Journal* C S Newbrier, Bay City

With the delegates are two or three Washington physicians and J E Jones, secretary of the National Capital Press Club, who represents the Washington *Evening Star* He is the only press representative traveling with the party

The party will leave Boston and stop at Saratoga, Niagara Falls, Detroit, Toledo, Cincinnati and Chicago

AT DETROIT

[From the Detroit Free Press, Sept 17]

The delegates to the Pan-American Medical Congress, which was held at Washington, arrived in the city yesterday morning before 7 o'clock The party, which numbered about sixty, were principally from Mexico, being accompanied by Samuel S Adams, chairman of the committee of arrangements, Dr H L E Johnson, chairman of the transportation committee They came by special train, which the United States Government has provided for the conveyance of the distinguished party from Washington to Chicago

At the depot they were met by the reception committee, composed as follows Dr E L Shurly, chairman, Drs A W Imrie, W G Henry, Hal C Wyman, E W Jenks, J Flinterman, A E Carrier, Donald Maclean, Leartus Connor, E A Chapoton, P J B Le Blanc, J V Becelaere, T A McGraw, H O Walker, F W Mann, C Henri Leonard, and Messrs M R Gatell, Herman Freund and F H Borradaile, and escorted to the Russell House where they sat down to breakfast

After a short rest the party were driven in carriages to the extensive laboratory of Frederick Stearns & Co, Twenty-first street, and were there received by Mr Stearns, Sr, who was awaiting their arrival

They visited twenty-four departments in the following order Mill room, fluid extract manufacturing, still room, fluid extract percolating room, fluid extract finishing room, pomade washers, pharmaceutical manufacturing, capsule room, stock room and analytical room, pill manufacturing room and gelatin coating room, sugar coating room, pill mass cutting room, Spanish office, pill finishing room, seidlitz room, pressroom, composing room, and compressed lozenge room, ointments, bottle washing room, filling room, filled stock room, packing and shipping room, cachet room and box factory, and stock room On the top of each of the doors to the different departments was a large printed card in Spanish describing the department, and the nature of the work performed there The doorways to the different departments were also decorated with the flags of the nations represented the Spanish colors being conspicuous

Special interest was manifested in the manufacture of hard and soft capsules and in the manufacture of pills The mechanical processes in use were entirely new to the strangers, and when they saw hundreds of pills turned out in a twinkling, as if by magic, and the gelatin of capsules formed, filled with the fluid and hermetically sealed in about the time it takes to swallow one, they could only utter their amazement They were impressed with the completeness of the lines of pharmaceutical products, with the magnitude of the establishment, its equipment, the system that was apparent everywhere and the scrupulous cleanliness of every department It took fully two hours to walk over the building after which the company were entertained at luncheon in the crude stock-storing room Time being limited, the refreshments had to be hurriedly partaken of They left about 12 o'clock

They also visited the great laboratories of Parke, Davis & Co and Nelson Baker & Co, where they were courteously received and hospitably entertained They were then driven round the city and to Belle Isle, and at 2 30 took luncheon at the Russell

In the evening they were entertained at a banquet at the Russell House The following day they were given a sail down the river, and left in the evening for Cincinnati

[Detroit Free Press, Sept 18]

AGROUND IN LAKE ST CLAIR —The visit of the delegates to the Pan-American Medical Congress came to an unpleasant ending last night and doubtless many wished they had omitted the last feature of the entertainment The delegates together with a number of local physicians and ladies took the steamer *Mary*, yesterday morning for a trip through the lake The party was entertained at the Oakland by Mark Hopkins but on the return trip the boat evidently lost her way, for she ran in too close to the Grosse Pointe shore and came to a standstill 300 feet from the club dock, running very hard aground All efforts to release her were without avail, and finally a boat was lowered and some of the local physicians went ashore to make arrangements for bringing the party back The street car company was apprised of the situation and sent out cars to convey the visitors to the Michigan Central depot, where their special awaited them It took some time to convey all in safety to the shore, and there was a great deal of consternation among the party while waiting for turns in the small boat The train was held and the delegates got away, although behind the scheduled time

AT CINCINNATI

[From the Commercial Gazette]

CINCINNATI, O , Sept 18, 1893

Mayor Mosby Monday morning received the representatives of the Pan-American Medical Congress There were about sixty in the body The delegates arrived in the morning in a special train, stopped at the Grand Hotel for breakfast, and made the City Hall their objective point They came in a tallyho and in carriages, and on alighting took possession of the Mayor's handsome reception room They had scarcely ensconced themselves in the heavy leather sofas and chairs when His Honor, arrayed in a new suit of black and a shining tile, stepped out of the private office Dr J C Culbertson, Chairman of the Reception Committee, Dr Comegys, President of the Academy of Medicine, the Health Officer and several other medical men, members of the Reception Committee, stood around ready to do honor to the distinguished visitors Dr Culbertson introduced the Mayor, who shook hands with each of the party, and then all adjourned to the handsome council chamber, where His Honor spoke as follows

"It is with a great deal of pleasure that I welcome the Pan-American Congress to our city I extend to you the warmest greeting of our citizens, and I want to thank you for your interest in studying our customs and laws Such interest is for our mutual benefit, and can not but help uniting the Americas in a firmer union As for your excursion, I feel and hope that commercial prosperity will follow it As for our hospitality, I wish to say that the city is yours If you see anything you want, take it, I will give you even our new City Hall "

The speech ended, the Congress took carriages to the City Hospital, where they went through the wards The College of Music was next visited, and President Peter Rudolph Neff had everything in good shape In the College proper all styles of classes were in recitation, and the Lyceum and Odeon had concerts In Music Hall the great organ was performed upon, and the only audience was the visitors Leaving the college, the visitors walked to Fourteenth street, where three electric cars awaited them These were run up Elm to the incline, and up that and on out to Burnet Woods, where the carriages, which had been sent on, took the members through the park and also through Clifton After a view had been taken of the handsome suburb a cut was made for the Zoological Gardens, where dinner was served

After dinner Avondale and Walnut Hills were driven through and then Eden Park and at the Art Museum a stop was made and a lunch served The Rookwood pottery was then examined, and a trip down the incline made Carriages were in waiting and conveyed the Queen City guests to the Grand, where after supper, the party took a special train for Chicago With the party was a colored man, Surgeon General for the Republic of Hayti Another (apparently colored) man was physician to the Khedive of Egypt, and a third, a handsome white man, was the medical adviser to the Emperor of Austria The two latter do not belong to the Congress, and joined the party accidentally in Washington

AT CHICAGO

The excursionists reached the Union depot, Chicago, on Tuesday, Sept 19 They were met at the depot by a committee consisting of Drs C W Earle, John B Hamilton, I N Danforth, Truman W Miller, Randolph N Hall, Cassius D Westcott, Frank C Greene and Geo Henry Cleveland This committee had arranged for the whole party at the Palmer House, but one of the Washington committees had arranged for breakfast for them at the Auditorium, but the *contretemps* was obviated by the party going in a body to the Auditorium for breakfast After breakfast they went to the banquet room, where they were formally welcomed by the Hon Carter H Harrison, Mayor of Chicago, who was introduced by Dr Chas W Earle, President of the Chicago Medical Society The Mayor made one of his characteristic speeches, which was well received

Dr Fernando Henrotin then bade the visitors welcome in French, Dr E J Gardner in Spanish, and Dr John B Hamilton in English Having been thus thrice welcomed, a brief response was made by one of the delegates, and the party was allowed to rest until evening

At 8 30 the hall and reception rooms of Kinsley's were thrown open, and the delegates were received by the General Committee of the Medical Society

The committee consisted among others of the following

Dr Chas W Earle, Dr John H Hollister, Dr Edmund J Doering, Dr Nicholas Senn Dr Archibald Church, Dr I N Danforth, Dr N S Davis Sr Dr John B Hamilton, Dr Truman W Miller, Dr D W Graham Dr J M Patton Dr R N Hall, Dr E J Gardner Dr L F Ingals Dr Edmund Andrews Dr Frank Johnson, Dr Frank Andrews, Dr Moreau R Brown Dr R N Isham Dr J B Murphy, Dr H Kellogg, Dr La Garde, U S A Dr C P Wertenbaker, M H S , Dr F C Greene Dr DeLaskie Miller Dr Wylis Andrews, Dr Frank Billings Dr H T Byford, Dr Sanger Brown, Dr G H Cleveland, Dr F C Hotz, Dr S H Stevenson, Dr Hoff, U S A , Dr Bayard Holmes Dr D R Brower, Dr J H Etheridge, Dr A R Reynolds Dr W E Clark, Dr E O Roler, Dr Ernest Hart and Sir Richard Webster

Many ladies attended the reception A male quartette sang funny songs, and a mandolin orchestra furnished instrumental music

On Wednesday the exercises began by a trip to the Chicago Medical College, where the new laboratory was inspected The party then visited the Cook County Hospital where luncheon was served, Dr J B Murphy presided There were some toasts, after which the Rush Medical, Physicians and Surgeons, Woman's, Policlinic and Post Graduate Medical Colleges were visited, and the Presbyterian Post Graduate and Policlinic Hospitals The day was finished at the Policlinic The visitors were escorted to their rooms at the Palmer House, and the great Pan-American Medical Congress had finished its program

MISCELLANY

Gift to a Hospital —St Luke's Hospital, Detroit, will receive $200,000 as a bequest from the late Samuel B Coyle of that city

Homeopathic College —The Louisville homeopathists have started a medical college in that city

Binghamton, N Y, hospital has been reopened, the city council having voted the money for its continuance

New Hospital at Winnipeg, Man —Winnipeg doctors are making strenuous efforts to have a general hospital established by the Dominion Government

West Chester Hospital —The managers of the West Chester county, Pa , Hospital have filed their application for the $10,000 voted them by the last legislature for the erection of a new building, with proviso that the management should first raise $5,000

Pennsylvania Hospital for Feeble Minded —The site for the State hospital for the care of feeble minded children has been selected near Franklin, Pa

Dr P O Hooper Resigns —Dr P O Hooper has resigned his position as superintendent of the Arkansas State Lunatic Asylum, the resignation to take effect some time within the next thirty or sixty days No reason is said to be given by the superintendent in his letter asking to be relieved of his charge The Arkansas Insane Asylum is the most important charity in the State

Dr Pozzi of Paris, the well known gynecologist, is on his way to Chicago, having been designated by the French Government to attend the World's Fair

Medical Society of the State of New York —The following business committee has been announced by the president of this Society, Dr Herman Bendell of Albany Dr Henry Flood of Elmira, Dr L Bolton Bangs of New York, Dr Edward Clark of Buffalo, to whom all communications regarding papers for the meeting of the society in February next may be addressed F C CURTIS, *Secretary*

Medical Club Election —At the first regular meeting of the Roswell Park Medical Club of Buffalo, the following officers were elected for the ensuing year president, Dr Julius H Potter, vice president, Dr George F Cott, secretary and treasurer, Dr James A Gibson Dr Potter read a paper on diphtheria and its latest treatment

A Hospital for Melrose, Mass —A charter has been issued from the office of the Secretary of State for the incorporation of the Melrose Hospital Association Royal P Barry is president of the new association, and Decius Beebe treasurer The hospital will be used for the needy sick and disabled of the town Those who are in a position to pay will be requested to do so Money so received will go to the maintenance of the hospital

Colorado Medical Library Association —DENVER, COL, Office of the Secretary, July, 1893 —The medical fraternity of Denver and Colorado are endeavoring, as the accompanying booklet shows, to build up a medical library in this city It is not necessary to call attention to the advantages which accrue to the profession of medicine through the establishment of a medical library Our remoteness from the centers of population makes the work we have undertaken difficult in many ways Your society can aid materially in this enterprise by sending us its proceedings Anything sent us will be acknowledged, placed on the shelves of the library and brought to the attention of its readers

Yours respectfully,
J T ESKRIDGE, M D, President,
HENRY SEWALL, M D, Secretary,
J C DANA, Librarian Public Library,
For the Association

Address, care Public Library, Denver, Col (The association will pay transportation if you wish)

The State Board of Health of Nebraska —The State Board of Health Sept 10 ruled against the issuing of certificates as physicians to graduates of Cotner University medical department, thus upholding the action of the board's secretary The board has passed this order "Your report in the matter of the medical college of Cotner University, together with other papers touching the same matter, having been under consideration of the State Board of Health, you are hereby notified that we affirm your decision and coincide with your conclusions that the number of clinics in connection with the college has not been sufficient to justify the recognition of its diplomas and we further recommend that as soon as this college has, in your judgment, complied with the requirements of the statutes its diplomas be recognized, and that all due encouragement be held out to this college to put itself upon a solid footing and to build up a strong medical institution

"It is understood that the college officers have secured a building near the main building and will open a hospital where patients may receive treatment free of charge A free dispensary is also to be opened in Lincoln, and by these additions the officers expect to satisfy the board that the law is being complied with"

Charity Hospital at Westchester, N Y —Although the Westchester Free Hospital has been open only a few days, hundreds of people have visited it, and each one has left a substantial donation Each afternoon finds it surrounded with a collection of swell turnouts and delivery carts Westchester has for the first time an institution on which people of all classes can unite, and a wave of charity has possession of the town

The secretary, William Hosea Ballou, announces the following medical board for the hospital year Consulting physicians, Dr Clement Cleveland, gynecologist, Dr J E Ellis, Dr Frank W Jackson and Dr W B James, consulting surgeons, Dr Joseph W Bissell, Dr Arnold Naudain and Dr Z E Lewis, out-patient department, Dr W C Deming, Dr Frank Anson Becker and Dr W B MacNichol, pathologist, Dr J S Thatcher

THE PUBLIC SERVICES

Army Changes Official list of changes in the stations and duties of officers serving in the Medical Department U S Army, from September 9, 1893, to September 15 1893

Major DAVID L HUNTINGTON, Surgeon U S A, is granted leave of absence for one month

Lieut Col CHARLES R GREENLEAF, deputy Surgeon General U S A, is granted leave of absence for two months, to take effect from August 25, 1893

Capt LOUIS A LA GARDE Asst Surgeon will upon the completion of his duties in connection with the World s Columbian Exposition, report in person to the commanding general, Dept of the Colorado, Denver, Col for duty as attending surgeon and examiner of recruits in that city

Lieut Col J V D MIDDLETON, deputy Surgeon General U S A, is hereby granted leave of absence for one month, to take effect on or about October 1, 1893, with permission to apply for an extension of fifteen days

First Lieut CHAMPE C MCCULLOCH Jr Asst Surgeon is relieved from duty at Ft Sam Houston Tex and ordered to Ft Ringgold, Tex for duty, relieving Capt JAMES E PILCHER, Asst Surgeon Capt PILCHER upon being relieved ordered to Ft Niagara N Y, for duty relieving Capt REUBEN L ROBERTSON Asst Surgeon Capt ROBERTSON upon being relieved, ordered to Ft Omaha, Neb for duty

Col J C BAILY, Asst Surgeon General is granted leave of absence for one month to take effect about the 5th instant

Major CHARLES L HEIZMANN Surgeon (Ft Douglas, Utah), is granted leave of absence for one month, to take effect between the 25th instant and the 5th proximo

Major J VAN R HOFF, Surgeon U S A, is hereby granted leave of absence for one month

First Lieut HENRY R STILES Asst Surgeon, is relieved from duty at Ft Omaha, Neb, and will report in person to the commanding officer, Ft Meade, S Dak for duty at that post

Capt CHARLES E WOODRUFF, Asst Surgeon leave of absence granted is extended four months By direction of the Secretary of War

Capt JUNIUS L POWELL Asst Surgeon, leave of absence granted is extended ten days

There are six vacancies in the Medical Corps of the Navy.

The Marine Hospital at Port Townsend was partially destroyed by fire on the 9th, at a loss of $3,500 The patients were removed to temporary quarters pending the construction of a new building

Marine Hospital Service —The importance of the work done by the Marine Hospital Service in keeping watch for cholera in Europe during this season has been undeniably great The latest reports received from its agents indicate that there is a good deal of the disease still on the continent in various places, while strenuous efforts are being put forth by the officials to conceal the facts Plainly this is no time for relaxation of efforts on the part of our quarantine and sanitary officers We have practically escaped cholera thus far, and we have learned much of value from last year s experience But unceasing vigilance alone can give us the assurance of continued safety —N Y *Tribune*

AMERICAN INEBRIATE ASYLUMS

Read before the Section of Neurology and Medical Jurisprudence at the Forty fourth Annual Meeting of the American Medical Association

BY T D CROTHERS, M D
SUPERINTENDENT WALNUT LODGE HOSPITAL, ETC, ETC
HARTFORD, CONN

Institutional care and treatment of inebriates began first in this country, and up to this time has attained a degree of development and prominence greater than that of any other country of the world There are in Great Britain over forty asylums where inebriates are received and treated, and at least ten or twelve more in Europe, three are in India, two in Australia and New Zealand, and two opium hospitals are in operation in China With the asylums in this country, the number will reach to about one hundred and twenty in the world It is difficult to ascertain the exact number for the reason that many of these asylums are irregular in their work, and are associated with reformatories, sanatariums and homes for mental diseases

In Europe they are often sectarian church homes, and in this country many are private enterprises, dependent on the caprice of the managers and their successes This is incident to every new work, and the formative stage, or the period of credulity that is always followed by the age of reason

Asylum care of inebriates implies a recognition of disease and curability, which has been mentioned and urged for over two thousand years of the world's history From the time of Hippocrates (and even before), down to the beginning of this century, the idea of drink madness and drink excesses being a disease, and curable by physical means, with restraint, has appeared in the science and literature of every age Dr Rush's writings in 1790 and 1809, seemed to have formulated the vague ideas along this line, although several European authorities carried the subject farther on they were practically unknown in this country, hence Dr Rush may be said to have given the first inspiration and practical direction to the doctrine of the disease and its curability

This idea was repeated in various ways, over and over again, until finally in 1846, Dr J E Turner appeared as the first pioneer to build an asylum and demonstrate this fact

Although the disease of inebriety had been recognized by a large number of eminent men in both this country and Europe, and asylums for their cure had been urged by the Connecticut State Medical Society of 1830, and the English Lunacy Commission of 1844, and others, the opposition of moralists and clerical reformers was so bitter and intense as to prevent any practical work This has continued up to the present, only growing less and less

In the year 1846, Dr J E Turner of Bath, Maine, a practicing physician, became interested in the need of an asylum, from an ineffectual effort to save an early friend who was an inebriate

He recognized the nature of the disease of inebriety and the need of hospital treatment and began an enthusiastic agitation of the subject

He began by petitions and solicitations for money and influence to build an asylum, appealing to the New York State Legislature for years before a mere recognition was given So intense was the opposition that clergymen denounced it from the pulpit, and many of the religious and secular papers condemned the theory of disease and idea of an asylum as insane and opposed by all common sense and judgment

At this distance, this period of denial and persecution appears like a glimpse of the dark ages, and the medieval spirit that opposed every new truth of science

Finally, after ten years of persistent effort, despite the most bitter opposition he succeeded in forming a company to build an inebriate hospital, with the late famous surgeon, Dr Valentine Mott, as president

In May 15, 1854, the first inebriate asylum in the world was chartered by the New York State Legislature Laws were passed giving power to hold inmates and charter was granted The city of Binghamton bought a farm of nearly 200 acres of land and gave it to this company Donations of lumber, stone and all kinds of building material were made on solicitation The corner stone was laid in 1858, of what was later a magnificent building, and at one time the finest type of castellated Gothic architecture in the world Six years later a part of the building was completed and opened for patients

The founder, Dr Turner, was a man of indomitable perseverance and tireless energy, who worked on without aid from others, begging money and material and superintending the construction of all the details of the building At length in 1864, this first asylum of the world was opened for the physical care and treatment of inebriates at Binghamton, N Y The principles of treatment on which it was established were simply remarkable in clear, defined, scientific conceptions of the nature and requirements of such cases Absolute restraint and control was provided, and no one was received for less than one year It asked no pledges or promises from the patient, it aimed to give each one positive protection and medical treatment The patients were locked in at night and only allowed out for exercise under the strict care of attendants Turkish baths were given twice a week, work rooms were provided for those of mechanical tastes Amusements of base ball, billiards, bowling and carriage drives were urged each day Each case was considered a suicidal case

Dr Pozzi of Paris the well known gynecologist, is on his way to Chicago, having been designated by the French Government to attend the World's Fair

Medical Society of the State of New York —The following business committee has been announced by the president of this Society, Dr Herman Bendell of Albany Dr Henry Flood of Elmira, Dr L Bolton Bangs of New York, Dr Edward Clark of Buffalo, to whom all communications regarding papers for the meeting of the society in February next may be addressed F C Curtis, *Secretary*

SUPERINTENDENT WALNUT LODGE HOSPITAL, ETC , ETC
HARTFORD, CONN

Institutional care and treatment of inebriates began first in this country, and up to this time has attained a degree of development and prominence greater than that of any other country of the world There are in Great Britain over forty asylums where inebriates are received and treated, and at least ten or twelve more in Europe, three are in India, two in Australia and New Zealand, and two opium hospitals are in operation in China With the asylums in this country, the number will reach to about one hundred and twenty in the world It is difficult to ascertain the exact number for the reason that many of these asylums are irregular in their work, and are associated with reformatories, sanatariums and homes for mental diseases

In Europe they are often sectarian church homes, and in this country many are private enterprises, dependent on the caprice of the managers and their successes This is incident to every new work, and the formative stage, or the period of credulity that is always followed by the age of reason

Asylum care of inebriates implies a recognition of disease and curability, which has been mentioned and urged for over two thousand years of the world's history From the time of Hippocrates (and even before), down to the beginning of this century, the idea of drink madness and drink excesses being a disease, and curable by physical means, with restraint, has appeared in the science and literature of every age Dr Rush's writings in 1790 and 1809, seemed to have formulated the vague ideas along this line, although several European authorities carried the subject farther on they were practically unknown in this country, hence Dr Rush may be said to have given the first inspiration and practical direction to the doctrine of the disease and its curability

This idea was repeated in various ways, over and over again, until finally in 1846, Dr J E Turner appeared as the first pioneer to build an asylum and demonstrate this fact

Although the disease of inebriety had been recognized by a large number of eminent men in both this country and Europe, and asylums for their cure had been urged by the Connecticut State Medical Society of 1830, and the English Lunacy Commission of 1844, and others, the opposition of moralists and clerical reformers was so bitter and intense as to prevent any practical work This has continued up to the present, only growing less and less

In the year 1846, Dr J E Turner of Bath, Maine, a practicing physician, became interested in the need of an asylum, from an ineffectual effort to save an early friend who was an inebriate

He recognized the nature of the disease of inebriety and the need of hospital treatment and began an enthusiastic agitation of the subject

He began by petitions and solicitations for money and influence to build an asylum, appealing to the New York State Legislature for years before a mere recognition was given So intense was the opposition that clergymen denounced it from the pulpit, and many of the religious and secular papers condemned the theory of disease and idea of an asylum as insane and opposed by all common sense and judgment

At this distance, this period of denial and persecution appears like a glimpse of the dark ages, and the medieval spirit that opposed every new truth of science

Finally, after ten years of persistent effort, despite the most bitter opposition he succeeded in forming a company to build an inebriate hospital, with the late famous surgeon, Dr Valentine Mott, as president

In May 15, 1854, the first inebriate asylum in the world was chartered by the New York State Legislature Laws were passed giving power to hold inmates and charter was granted The city of Binghamton bought a farm of nearly 200 acres of land and gave it to this company Donations of lumber, stone and all kinds of building material were made on solicitation The corner stone was laid in 1858, of what was later a magnificent building, and at one time the finest type of castellated Gothic architecture in the world Six years later a part of the building was completed and opened for patients

The founder, Dr Turner, was a man of indomitable perseverance and tireless energy, who worked on without aid from others, begging money and material and superintending the construction of all the details of the building At length in 1864, this first asylum of the world was opened for the physical care and treatment of inebriates at Binghamton N Y The principles of treatment on which it was established were simply remarkable in clear, defined, scientific conceptions of the nature and requirements of such cases Absolute restraint and control was provided, and no one was received for less than one year It asked no pledges or promises from the patient, it aimed to give each one positive protection and medical treatment The patients were locked in at night and only allowed out for exercise under the strict care of attendants Turkish baths were given twice a week, work rooms were provided for those of mechanical tastes Amusements of base ball, billiards, bowling and carriage drives were urged each day Each case was considered a suicidal case of insanity, requiring long medical care and restraint No question of honor, or appeals to the pride was considered, but in all, the use of exact means and measures were carried out with military exactness

These methods of treatment were far in advance of that time, and even to-day are just beginning to be recognized as the latest teachings of science The principles plan of organization, and treatment, although endorsed and supported by its distinguished presidents, Drs Valentine Mott and John W Francis, of New York, and Chancellor Walworth of Saratoga, created much difference of opinion and opposition The patients themselves, after the immediate recovery from the effects of spirits, protested against the confinement and doctrine of disease, and sought in every way through their friends to break up the methods of treatment As many of them had been influential men, and had prominent friends, a storm of the most bitter opposition began against the founder Two separate views or theories of treatment became the center of intense feeling The asylum and management insisted that each case was more or less diseased and should be under absolute control and restraint for long enough time to effect a permanent cure The patients and their friends insisted that while the case might be diseased, his recovery depended largely on his liberty and promise to get well That restraint was an irritation and an injury, also that appeals to his honor and manhood were the real agents for final cure The founder and his friends insisted on long, absolute restraint and military control of the case, with the application of means and measures above all caprice and emotional changes of the patient The opposition urged that restraint should be only nominal at first, and length of treatment vary with the man and his disposition, to which should be added moral appeals and moral remedies

After a long, bitter struggle, the board of management changed and adopted a practically free and easy plan of treatment and Dr Turner and his friends were turned out The central object was to make the asylum popular with the patient This unfortunate controversy gave new impetus to the moralists, and those who doubted the disease theory, and they joined in a wild crusade to show the folly of such institutions The bitter controversy which gathered about the management of this asylum attracted the politicians, and the noted William M Tweed of New York City, and others became directors

All this time the asylum was crowded with patients and the income was diverted to secure personal ends Finally in 1867 the board of management deeded the property to the State of New York for one dollar, ithout the advice or consent of any one From that ime a series of misfortunes followed during which
seven superintendents were in cl in eleven years
Then the State changed the asy insane hos
pital, and a political governor, ion of the
act, called the inebriate asyl Not-
withstanding the conflicts of pul d the
changing methods of treatment iced
men in charge, large numbers of y
permanently cured, as was clearly
tics gathered the last years of its
inebriate asylum The enthusiasm
tered about this work at different ti
the idea of failure and condemnati
treatment for inebriates was spread t

Had the physical treatment of the inebriate been a theory, this would have been its final death But, like all other great enterprises of the world, the death of Binghamton Asylum marked the birth of a large number of similar asylums, some of which are doing grand work in the world The great fact that inebriates were diseased, requiring positive hospital care, was demonstrated to the world by Binghamton Asylum beyond all question

The advent of Binghamton Asylum was felt all over the world, even in far away Australia, an asylum was opened in 1859 that is still in existence In Europe many small asylums began, although opposed as bitterly as in this country, yet they soon came under church control and gave great prominence to the moral and ethical side, and thus escaped the criticism others received Long before Binghamton Asylum disappeared, a number of embryo institutions came into existence, many of which died from weakness and inability to bear the shock of opposition Others struggled and are living to day One of these early asylums was the Washington Home of Boston, which began in 1857 as an inebriate lodging-house in the center of the city of Boston

After years of opposition and serious trials it came under full medical management as a scientific hospital, and is now the oldest asylum in the world Its late superintendent, Dr Day, has had the largest experience in the management and cure of these cases of any person living This hospital has had its wild storms of criticism and persecution incident to every new advance of science, but now receives about four hundred patients yearly The second large asylum in the world that began in those early days and is doing good work, is Kings County Inebriate Home, of Brooklyn, N Y, Dr Blanchard, superintendent This was opened in 1867, and, from small beginnings, has gone on to be a magnificent hospital crowded with patients The disease of inebriety and the need of positive restraint and medical cure are the cardinal points of its management

The Chicago Washingtonian Home was opened in 1867, and has been in successful operation up to the present

The Franklin Home of Philadelphia, Pa, was opened in 1872, and is receiving a large number of cases every year

Walnut Lodge Hospital at Hartford, Conn,
ned in as a private corporate asylum,
bec inent, although smaller than

ct hospitals in the world
ebriate Over a thousand
trea yearly at these

and disease as a compromise of half vice and half disease, is still the center of controversy The first three asylums and a rapidly increasing number of small private homes and hospitals retain the principles and approximate to the plans of treatment laid down at Binghamton in 1864, while the others have no fixed scientific conceptions of the nature and needs of the inebriate or his malady

Notwithstanding the misfortunes of the first hospital and its founder, a large number of similar places have been organized and managed with success

As in all new enterprises, many of these hospitals must suffer from non-expert management and be organized on some theory of the nature and treatment of inebriety not founded on correct study and experience After a time they are abandoned or changed to homes for nervous cases and insane Over fifty different hospitals for inebriates have been established in America More than thirty of this number are in successful operation, the others have changed into insane asylums, water cures, etc Three large buildings or institutions are practically "faith cures," where all physical remedies and means are ignored Several asylums are called homes for nervous people, to conceal the real cause, and thus protect the patients from the supposed stigma of inebriety Others are literally lodging houses, where the inmates can remain a few days and recover from the effects of spirits Several places make a specialty of opium cases, in some the treatment is empirical In only a few of these hospitals is the disease of inebriety studied and treated on a scientific basis the others are passing through the ordeal of "elimination and survival of the fittest" incident to every new advance of science In many of the States large public hospitals are projected and awaiting pecuniary aid from the State or from other sources

Of the forty asylums in operation in Great Britain to-day, only a very small number are conducted on scientific principles, the others are church homes and charitable retreats where temporary care is given for immediate necessities A thorough scientific hospital has been doing grand work in Melbourne, Australia Another has been organized in New Zealand under a competent board of medical men, and both of these hospitals are a credit to the skill and judgment of the managers Two very well managed asylums are in operation in Germany and one in Switzerland A number of similar hospitals have been projected in Norway, Sweden and France In the latter country the inebriates are sent to insane asylums and placed in a ward by themselves This has become an abuse which the superintendents of asylums have strongly denounced The inebriate asylums of Europe are nearly all private institutions or under the control of churches and temperance societies The Dalrymple Home, near London, is one of the largest and best equipped in Europe

All these places, both at home and abroad, are yet in their infancy, not one of them are able to do the work that should be accomplished, because of the unjust criticism and obstacles which they have to overcome The results of treatment in the few scientific hospitals for inebriates are most encouraging The first statistical study was made at Binghamton Asylum in 1874 The object was to find out how many persons who had been under treatment continued temperate years after Accordingly, 1,600 circular letters were addressed to friends of patients who had been under treatment five years before, asking the present condition of the patient The answers indicated 62½ per cent as yet temperate and total abstainers This result, after an interval of five years, was clear evidence that a large per cent would, in all probability, remain cured during the remainder of life

Dr Day of Washingtonian Home, made a similar study of 3,000 cases who had been under treatment ten and more years before, and found over 32 per cent yet sober and temperate

Dr Mason of Kings County Inebriate Home, examined 2,000 cases who had been away from the asylum for ten years, and found 34 per cent of all cases yet cured He expressed great surprise at this result, as most of the cases were considered incurable at the time of treatment Other observers have made studies of a smaller number of cases with similar results

The most careful authorities of this country and Europe agree in the statement that fully one-third of all cases who come under treatment for periods of three months or more are permanently restored Other institutions where inebriety is treated as a vice, or by empirical methods, claim 80 and 90 per cent of recoveries It is needless to add that all such statements are not supported by published statistics In view of the chronic character of these cases and the imperfect means of treatment, the results so far are encouraging, and indicate great possibilities in the future from a better knowledge and control of these cases

Such is an outline view of the history and present condition of asylums *in this country* The rampant empiricism which is so prominent to day is indirectly rousing up a new interest in all asylums for inebriates The increasing crowds of relapsed cases whose faith in the gold cure specifics has been misplaced, are rapidly filling up all asylums, and come in a measure prepared to accept physical treatment and to appreciate the need of means and remedies There are ideals of the coming means and appliances essential for the successful treatment of inebriety towards which a few institutions are struggling Each year's experience brings larger and clearer conceptions, and each institution is becoming more adapted for scientific work in this field

An outline of the scientific treatment of inebriety in asylums in America will describe some part of the treatment common to each, but not yet attainable in its entirety, because of the numerous obstacles and want of support from public opinion and other conditions

The situation of an asylum in the suburbs of a city or in the country near large centers, with ample grounds for retirement and quiet living, are essentials A proper building, equipped with baths and all the appliances for comfort, with means of amusement, joined with ample legal power to hold the patient a year or more, are equally essential They should be called hospitals, not only in full recognition of their physical disabilities, but as places where every condition of life can be regulated and every surrounding can be made to aid recovery and restrain Literally a quarantine hospital, where isolation and removal of all the exciting causes, combined wit appropriate treatment to build up and restore deranged functional activities of the organism, c be obtained The time of treatment should be fro of insanity, requiring long medical care and restraint No question of honor, or appeals to the pride was considered, but in all, the use of exact means and measures were carried out with military exactness

These methods of treatment were far in advance of that time, and even to-day are just beginning to be recognized as the latest teachings of science The principles plan of organization, and treatment, although endorsed and supported by its distinguished presidents, Drs Valentine Mott and John W Francis, of New York, and Chancellor Walworth of Saratoga, created much difference of opinion and opposition The patients themselves,after the immediate recovery from the effects of spirits, protested against the confinement and doctrine of disease, and sought in every way through their friends to break up the methods of treatment As many of them had been influential men, and had prominent friends, a storm of the most bitter opposition began against the founder Two separate views or theories of treatment became the center of intense feeling The asylum and management insisted that each case was more or less diseased and should be under absolute control and restraint for long enough time to effect a permanent cure The patients and their friends insisted that while the case might be diseased, his recovery depended largely on his liberty and promise to get well That restraint was an irritation and an injury, also that appeals to his honor and manhood were the real agents for final cure The founder and his friends insisted on long, absolute restraint and military control of the case, with the application of means and measures above all caprice and emotional changes of the patient The opposition urged that restraint should be only nominal at first, and length of treatment vary with the man and his disposition, to which should be added moral appeals and moral remedies

After a long, bitter struggle, the board of management changed and adopted a practically free and easy plan of treatment and Dr Turner and his friends were turned out The central object was to make the asylum popular with the patient This unfortunate controversy gave new impetus to the moralists, and those who doubted the disease theory, and they joined in a wild crusade to show the folly of such institutions The bitter controversy which gathered about the management of this asylum attracted the politicians, and the noted William M Tweed of New York City, and others became directors

All this time the asylum was crowded with patients, and the income was diverted to secure personal ends Finally in 1867 the board of management deeded the property to the State of New York for one dollar, without the advice or consent of any one From that time a series of misfortunes followed during which seven superintendents were in charge in eleven years Then the State changed the asylum to an insane hospital, and a political governor, in justification of the act, called the inebriate asylum a failure Notwithstanding the conflicts of public opinion, and the changing methods of treatment by inexperienced men in charge, large numbers of persons went away permanently cured, as was clearly shown by statistics gathered the last years of its existence as an inebriate asylum The enthusiasm which had centered about this work at different times reacted, and the idea of failure and condemnation of asylum treatment for inebriates was spread far and near Had the physical treatment of the inebriate been a theory, this would have been its final death But, like all other great enterprises of the world, the death of Binghamton Asylum marked the birth of a large number of similar asylums, some of which are doing grand work in the world The great fact that inebriates were diseased, requiring positive hospital care, was demonstrated to the world by Binghamton Asylum beyond all question

The advent of Binghamton Asylum was felt all over the world, even in far away Australia, an asylum was opened in 1859 that is still in existence In Europe many small asylums began, although opposed as bitterly as in this country, yet they soon came under church control and gave great prominence to the moral and ethical side, and thus escaped the criticism others received Long before Binghamton Asylum disappeared, a number of embryo institutions came into existence, many of which died from weakness and inability to bear the shock of opposition Others struggled and are living to day One of these early asylums was the Washington Home of Boston, which began in 1857 as an inebriate lodging-house in the center of the city of Boston

The Chicago Washingtonian Home was opened in 1867, and has been in successful operation up to the present

The Franklin Home of Philadelphia, Pa, was opened in 1872, and is receiving a large number of cases every year

The Walnut Lodge Hospital at Hartford, Conn, was opened in 1878 as a private corporate asylum, and has become prominent, although smaller than the rest

These five are the largest hospitals in the world for the treatment of the inebriate Over a thousand patients are received and treated yearly at these institutions

The Washingtonian Home of Boston, the Kings County Asylum of Brooklyn, N Y, and Walnut Lodge at Hartford, Conn, regard the inebriate as diseased, and treat such cases on broad scientific principles

The Chicago Home and the Philadelphia Home and some other asylums believe in the prayer pledge and moral influences as the most valuable of all means and remedies Also that a short residence in the hospital is better than long treatment Medicines are only used for temporary purposes

These two classes of asylums represent the same old battle which greeted the first asylum at Binghamton, only less violent The question of vice and disease as a compromise of half vice and half disease, is still the center of controversy The first three asylums and a rapidly increasing number of small private homes and hospitals retain the principles and approximate to the plans of treatment laid down at Binghamton in 1864, while the others have no fixed scientific conceptions of the nature and needs of the inebriate or his malady

Notwithstanding the misfortunes of the first hospital and its founder, a large number of similar places have been organized and managed with success

Such is an outline view of the history and present condition of asylums in this country The rampant empiricism which is so prominent to day is indirectly rousing up a new interest in all asylums for inebriates The increasing crowds of relapsed cases whose faith in the gold cure specifics has been misplaced, are rapidly filling up all asylums, and come in a measure prepared to accept physical treatment and to appreciate the need of means and remedies There are ideals of the coming means and appliances essential for the successful treatment of inebriety towards which a few institutions are struggling Each year's experience brings larger and clearer conceptions, and each institution is becoming more adapted for scientific work in this field

An outline of the scientific treatment of inebriety in asylums in America will describe some part of the treatment common to each, but not yet attainable in its entirety, because of the numerous obstacles and want of support from public opinion and other conditions

The situation of an asylum in the suburbs of a city or in the country near large centers, with ample grounds for retirement and quiet living, are essentials A proper building, equipped with baths and all the appliances for comfort, with means of amusement, joined with ample legal power to hold the patient a year or more, are equally essential They should be called hospitals, not only in full recognition of their physical disabilities, but as places where every condition of life can be regulated and every surrounding can be made to aid recovery and restrain Literally a quarantine hospital, where isolation and removal of all the exciting causes, combined with appropriate treatment to build up and restore the deranged functional activities of the organism, can be obtained The time of treatment should be fr six months to two years, and be governed by the condition of the patient and extend to a legal control on parole for a long time after leaving the asylum In Connecticut the law gives control over all committed cases for three years, whether on parole or otherwise in the limits of the State

The hospital should provide exact military restraint with duties and responsibilities, rewards and punishments suited to the condition and capacity of the case, also work, amusement and occupation, both mental and physical, as medicinal agents Every condition of life should come under exact military control, baths, exercise, sleep, food and medicines all to be regulated and applied uniformly Each one should be treated as suffering from profound disease of the brain and nervous system requiring long rest and building up The general treatment should begin with an examination and inquiry of the facts concerning his past life and present condition These examinations should be repeated every few weeks, because of the rapid changes and errors which are impossible to guard against in the first and later examinations The use of spirits should generally be abandoned very early in the treatment, and the return of the drink paroxysm anticipated by the use of drugs, baths, exercise and special control

Many of the paroxysmal drinkers are practically epileptics and require similar treatment They are suffering from grave disturbances of the physical centers, and physical remedies are required in addition to other means Other cases are delusional maniacs and paranoiacs out of harmony with every condition of natural, healthy living, and unable to correct and adjust themselves to such conditions In others, nerve exhaustion is at the bottom of the drink impulse, inherited tendencies, reflex irritations, and many complex conditions which can only be discovered and treated in hospitals When these are treated the causes are removed, and the alcoholic soil is exhausted and dies away

States of poisoning from stupor to full delirium are made the subject of special treatment, according to the experience and theories of the physician These acute symptoms followed by chronic conditions, require equally special remedies and means

These are some of the general ideals in treatment to which every scientific asylum is moving All asylums suffer for want of ample legal authority over their cases for sufficient time to secure permanent results Public opinion regards asylums as of only temporary, and in most cases of doubtful value The theories of their work are openly termed "fads," and supposed to be founded on some mercenary or selfish purpose The pulpit, press and ultra reformers pass by on the other side, like the Levite Public patronage is withheld, and most all asylums depend entirely on the income of patients for support Hence they are more or less crippled in every way Many asylums suffer from poor location, bad buildings and surroundings, inability to classify their inmates and apply special treatment to each one In many places baths and systematic exercises can not be secured The nutritive hygienic and physical treatment can not be carried out on the ideals of the managers, hence many asylums are using the means within their power in anticipation, and looking forward for larger and more perfect facilities

The treatment of inebriety not only includes everything found valuable in hospitals for the insane, in reformaories of the most advanced type and in the modern sanitarian and homes for neurasthenics The essentials for treatment in each of these classes are required for the inebriate The asylum managed on the scientific plan of providing for the requirements of each case, must have the power of control, and special buildings the same as to the hospitals for the insane, the discipline and management of the modern reformatory and the appliances of the best sanitarians and private homes, then it can approximate to a measure of success in the treatment, that at present is only in outline American asylums are leading the world in these directions of practical work, and while no one has combined only in the crudest way these appliances, many asylums are approaching it yearly Asylums all over the world are at the beginning and infancy of their existence A great deal of preparatory work must be, done before they can reach the first stage of scientific work The moral remedies by appeals to the will power and morals of the case must pass away The delusions and palsy of the higher brain centers must be recognized, and dissolutions beginning in the ethical centers extending down to all the lower faculties must be studied The great fog banks of metaphysical theories of free will, moral depravity vice and wickedness, must disappear from all conceptions of inebriety, and its practical management in asylums Asylums and managers who act on the theory that the inebriate is half wicked and half sick are crippled Asylums and managers who attempt by drugs or moral appeals to restore and cure the victim are still far back in the stage of credulity The specific vaunter, who professes to break up the symptom for drink as if it were the disease itself, is an empiric, either ignorant or by design Asylums and managers who teach dogmatically the nature of inebriety and its only true remedies, are not very far along in their scientific work Asylums who claim large percentages of cures from certain means and remedies are nc worthy of confidence

Inebriety is found, when carefully studied, to be the most complex neurosis of modern research, dependent on heredity and many physical causes, also physical condition and environment that are not clear to the most minute study Asylums for treatment so far, by isolating the patient place him in the best condition for study of conditions and applying means for relief

The more thorough this study, the wider the range of causes appear, together with the means and methods of relief The most advanced asylum of to-day follows a general prospective plan of treatment, and has no specifics or no special theories that are not open to change and re-adjustment Beside a few general facts, which stand out like mountain peaks in a new land, all the intervening space is unexplored No one can speak dogmatically as to where inebriety begins and what the exact causes may be No one can explain the varied phenomena of drink storms, of the action of spirits on the brain, of the power of heredity, of the brain condition which demands relief by the craving for neurotics, of the sudden cessation of this drink impulse under unusual circumstances, of its equally sudden outburst from causes unknown Even in asylums the same uncertainty exists Cases that seem restored relapse, and others that are considered incurable become restored, showing that our present knowledge is very imperfect, and the known is comparatively nothing in contrast with the unknown

Running through all this phenomena of inebriety is an outline of a uniform movement of cause and effect, of events following each other according to some law, good examples are the periodicities of the drink impulses, and the outbreak of such impulses from the presence of certain conditions that can be foreseen and studied Patients under care in asylums present a remarkable uniformity of symptoms and progress that is often startling to the student Not unfrequently such cases can be anticipated and the results of treatment known far in advance The drink symptom is dependent on some conditions of brain degenerations and changes It will suddenly die out and disappear under the most adverse conditions and surroundings Examples are numerous of persons who become temperate sign pledges, and stop all use of spirits under the most unfavorable circumstances Every temperance and revival meeting furnishes illustrations of persons who are restored permanently, although the same means have been used many times before with no results

Persons are known to stop drinking from the slightest supposed reasons, and in all these cases the last means used are credited with being the active causes The true explanation in all these cases is that some change or evolution of brain function has occurred and the drink symptom has died out It is not the last prayer pledge or solicitation of others, or the last drug or remedy of special means used that has caused this change Other and more obscure causes are at work, and the time comes when their action is apparent in the cessation of the drink impulse Physicians in charge of asylums recognize this fact, and realize that their best efforts are in building up the brain and nervous system, and placing the organism in the best possible condition for both organic and functional change Remedies directed to the drink symptom are never curative, a dose of mercury acting on the liver is a rational method, more so than bromid to check the drink impulse

Asylum study of these cases show that inebriety is often a symptom or phase of a neuroses which may break out and change to some other form General paralysis, melancholy, and many forms of insanity, together with tuberculosis, and various neurotic affections follow frequently on the subsidence of the drink craze

The statement that the gold cure specifics are followed by an increased number of insane among those who have used the treatment must be a literal fact The proof of such a statement is found in the experience of every asylum, and the general principles of neurotic diseases The number of such persons can not be easily determined, but the more powerful the narcotic used to stop the drink symptom, the more certain insanity and profound degenerations of the brain centers will follow

All asylums for inebriates suffer from the large number of incurable inmates Persons, who, after an uncertain course of treatment go away, relapse, and condemn the asylum for their failure Much of the current opinions concerning asylums are formed by the irresponsible statements of incurables Such persons seem to take pleasure in denouncing asylums in every place, and boasting of the intrigues of its inmates On the other hand, persons who have received substantial benefit conceal all reference to their treatment and residence in an asylum The result is that, all institutions are judged by the unthinking public from the statements of those who have failed to receive any benefit from its work Unthinking physicians who suppose that the control of the drink craze is the central object of treatment often lend their influence to unfavorable criticism of asylum work This, joined with bitter condemnations of moralists, complicate and increase the difficulties of every practical asylum, trying to understand scientifically this new field of medicine

American asylums have many advantages over all foreign institutions, in freedom of caste and prestige, also in ability to follow independent lines of work and rise above the prejudices and opposition of those who dread change and advance Some general conclusions may be stated, as follows

1 The asylum care and treatment of inebriates began first in this century, and has grown and extended to all civilized nations of the world

2 American asylums have developed the disease theory and the practical character of physical treatment in institutions, beyond that of any others in this field

3 Asylums in this country represent nearly all stages of development and early growth, from infancy and childhood, with its feeble conceptions and infantile efforts, to the boastful assumption and over confidence of youth, on to the dawning truth of early manhood when reason and judgment begin to reign

4 A few of these asylums discern some great outline truths which may be stated with confidence as ideals towards which there is a rapid movement

5 Inebriate hospitals must take the place of jails and station houses

Such places are dangerous in their mental and physical surroundings by intensifying the degeneration and removing the patient beyond hope of recovery They are in many cases literal training stations for mustering armies of chronic maniacs that never desert or leave the ranks until crushed out forever

6 Inebriate hospitals should receive the incurable inebriates and make them self supporting, and build them up physically and mentally

They would relieve the taxpayer and relieve society of untold burdens of sorrow and misery

7 Inebriate hospitals should receive the recent cases and place them in the highest conditions of enforced health and vigor, and thus return a large number to health and sobriety again

8 Inebriate hospitals can and should be self-supporting when once established They should be managed on scientific business principles, like military training schools

9 Inebriate hospitals should be built from money raised by taxes on the sale of spirits, on the principle that every business should be obliged to provide for accidents which grow out of it

10 These are the realities which every inebriate hospital is approaching and which all experience points out as practical and literal in the near future

11 The inebriate hospitals of to day are only in the infancy of their work, contending with great opposition and prejudice, misunderstood, condemned, and working against innumerable obstacles

12 Lastly, there is an intense personality in inebriate hospitals to each one of us

They may bring salvation and restoration to some one near and dear

They may be fountains of healing whose influence shall cross and influence our pathway in many ways

13 Inebriate hospitals and their work are the great new lands which only a few settlers have reached They are calling to us to come up and occupy, and thus help the race on in the great march from the lower to the higher

Dr J K King Watkin's Glen—The essayist deserves great praise and credit for his long and patient work in this often unthankful line The doctor stands eminent in this line of work I have had opportunity to watch him very closely many years, and I consider him probably the best representative in this country on the view of inebriety being a disease I do not know how many of us would go as far as he does in that line, but certainly he has done advanced work and has brought out that side I have had a good deal of experience myself with these cases in various forms of treatment, and I seem to recognize in them two great elements one is the element of disease which is a form of neurasthenia, and the other is the element of habit I recognize habit as entering very largely into this thing, and there is no question but that habit after a time may become a disease Now the methods of treatment lie in two lines one is that of public inebriate asylums and the other of private institutions The question is which is to take the advance The public institutions are always subject to the danger that Buffalo and Binghamton have met, that is, getting under the influence of politics and following the unfortunate history of the asylum of which Dr Dewey was the head Private institutions lack one great quality of the public, that is, the ability to hold and retain the patient for a long time The doctor has mentioned the length of time, and it seems to me from my experience that time is a great element in these cases I have never found much difficulty in breaking up what you might call the disease Turkish baths and other things, building up the system, etc , answer that purpose, but the difficulty is to retain them long enough, until the habit is broken off and until the moral character and the physical strength are established sufficiently for them to stand and let it alone There lies the secret When we can solve that question, we will have no difficulty in curing a great many, but the difficulty is to retain them long enough Just as soon as a man who is accustomed to drinking gets fairly over it, his spirits rise at once and he thinks he is a free man and he is capable of going anywhere and having no trouble in the future, and he again rushes into temptation, and before he knows it is drinking The fact is, the institutions do not retain the patients long enough to establish their physical and moral character The doctor's idea of a State institution supported out of the funds that come from the sale of liquor is a very good one, but the question is, how long before it can be carried out? It reminds me of something that I saw when in Oklahoma last fall In one of the principal streets in Oklahoma city there was a very large saloon where everybody seemed to go, and right overhead was a Keeley cure, so they went right together, they got finished up downstairs and went upstairs to recover So I am afraid it will be in this question of establishing asylums out of the money that is received from the sale of liquor

Dr J G Kiernan—The history given by Dr Crothers is exceedingly interesting, and he mentioned some matters which were noteworthy in regard to the New York experience He did not, however, call attention to one of the most peculiar performances under Tweed and the régime, which was the attempt to reform an inebriate physician by placing him at the head of the inebriate asylum of Binghamton, the gentleman being imported for that purpose from Chicago I may say here that the Washingtonian Home in Chicago is a theme of ridicule It is notoriously only a sobering up place, but so delightfully conducted that little arrangements of this kind crop up now and again, the inmates go off on a spree and their absence is first discovered in the police station No attempt is made at treatment, except a certain amount of moral suasion and the medical agency of the miraculous pre-Raphaelistic chart which the head of the institution has hanging on the wall, and which he descants on to the admiration of the inebriates

Dr Crothers ignored one fact, i e , that between 1864 and 1882 there existed what may be very well called the Philistine era of American psychiatry That was the era when every bit of insanity was crammed into a very short Procrustean bed, and medical societies seemed the mouthpieces of mobs to enunciate certain lynch law doctrine with regard to the insane It seems to me not a few of those blind sprees resemble in a great many of their characteristics the period of stupidity that occurs in many epileptics The reference to certain cases healed by prayer, etc , brings into consideration another element the doctor did not take into account Every one knows that under certain conditions, while the subject is not hypnotized, he is in a peculiar state of mind and peculiarly liable to suggestion That suggestion, that conception, coming under those conditions, dominate the man when nothing else will With regard to the legal status of the question, it is the same as with the criminal The inebriate can not be properly taken care of any more than the habitual criminal, until he is regarded on the same level as the insane Under our law in Illinois there is one very curious anomaly The inebriate is not for custodial purposes an insane person, while civilly he is, because when a man becomes an habitual drunkard you have a guardian appointed just the same as over an insane person or minor In other words, the disease theory, and it can be regarded as nothing else, is taken into account in what might be called the civil aspect of the subject, but in what might be called the criminal aspect it is totally ignored

Dr Clark Gapen, Omaha, Neb —I would like to say a word in regard to the suggestion of police control in these cases I am fully and heartily in accord with the doctor that this subject should be regarded and treated as a neurosis I think I can go as far as any one in the acceptance of that theory In my mind it is simply a vaso motor neurosis usually induced by long continued use of alcoholics, but sometimes the neurosis occurs without such influences, and seems simply to spring up, but I think that especially should there be a different control in cases of this kind from ordinary police cases Washington is the only city in the country that has adopted that police control The superintendent of police there takes this view of it and has arranged and equipped his department with reference to the management of those cases outside of the police station He does not take those cases to the police station unless it is absolutely necessary and the individual has no other place to control him temporarily As to the view that Dr Kiernan has just expressed, I think that is simply deficiency in the law, the law is simply behind science in that respect Chronic inebriety, that is this special form of temporary insanity, should for all purposes of control be regarded entirely as other forms of insanity are

Dr J E Emerson—I have one criticism to make It seems to me the doctor is in error in saying that there is such a disease as the drink disease I think it would be much more correct judging from my own observation, to say that the tendency to drink arises from a variety of morbid conditions, of conditions of imperfect development, which manifest themselves in some form of tendency towards indulgence in narcotics not necessarily a disease, but resulting from various conditions I do not think we can yet say that there is a disease One man has spasmodic paroxysms of drink, another man simply has a feeble will and falling in with boon companions, gets to drinking I think they should be classed as an entirely different condition Still I think we must all agree that there is a physical basis, either in imperfect development, or you may say in a condition of partial degeneration of the general nervous system, lowered tone, at least a physical basis

As regards the possibility of restraint which has been spoken of, our laws in Michigan provide for it, but in a very peculiar way They provide for the appointment of a guardian on the application of any near relative, any blood relative or husband or wife, this guardian under the order of the judge of the probate court may send such patients to any hospital, asylum or sanitarium for treatment, to be retained there at the option of the guardian, with the proviso that the guardian must make a report whenever called upon by the judge of probate who sends the case, or at stated intervals of six months I have in very many instances endeavored to get friends to place their relatives under the provisions of this law, but have never yet succeeded, although I have recommended it in many instances The judge of probate has been invoked and has simply said he could not carry out the provisions of the law Why, I never could find out

Dr John G Reed—I have been very greatly interested in Dr Crothers' paper and almost as much so with the comments upon it For some time I have been giving some extra attention to this department of neurology, and it is very singular how one changes his mind as he comes in contact with men I, at first, under perhaps the influence of enthusiasm, supposed that I had established some principles that would be abiding, and when I came to test them by the opinions of others, I was disposed to change them a good deal It reminds me a good deal of the saying that the friend of to day is the enemy of to-morrow and the enemy of to day is the friend of to-morrow It brings up the idea that this department of neurology is in a formative stage and that we hardly have any well defined principles of general application except in theory and those not well tested by clinical data The gentleman on my right, taking exception to saying that we have the drink habit disease, or that the drink habit should be called a disease, seems to me to be somewhat in error I hardly know how you will avoid using the term in the investigation of so broad and deep a subject It seems to me that the multiple conditions are those of constitutional or congenital deficiency, which finally blooms out in inebriety, and that this should as much be called a disease as those conditions which produce epilepsy and other classified neurotic conditions

Dr W H Wells, Marshfield, Wis —The paper just read is very interesting and very important to us all, and there are two views that might be taken of the neurosis side of the question, as to whether the neurosis is primary in the majority of cases, or whether it is acquired Now I think there are two classes that we have, one in which the neurosis is primary and a still larger class in which it is acquired from the constant habit of drinking As one of the members, in advocating the neurosis and sanctioning that view said, in the majority of cases it is brought on by the habit of drinking I think it is well established that this habit of drinking can be acquired, and the constant habit then does produce a neurosis The habit of drinking we can acquire the same as we can acquire habits of eating We can acquire a taste for articles of food that when we first begin to eat are very disgusting, and it seems to me that in the majority of cases the habit and the neurosis are acquired rather than that it is a primary neurosis You take the child born of drunken parents and the disease may be direct, primary and hereditary, while another boy may start out being healthy in all respects and thrown in the company of drunkards and the habit gradually fixed upon him, although he begins in a perfectly normal way and having no desire for it, but the desire is acquired and finally produces a neurosis that perhaps would require constant treatment in order to cure

Dr William Thomas Bishop, Harrisburg, Pa —I began to be a temperance reformer on the reform idea After a while I came to the good, sound, sensible idea that drunkenness was a form of insanity as much as horse stealing or any other similar disease, and I think the mistake that they make is simply trying to get away from the fact and trying to make a compromise I think that there is where the whole foundation is and the nearer you get back to it as medical men and recognize it as a fair and square issue, that it is a disease and that it is a form of insanity, that the law which governs it is the same as any other phase of insanity and the restraint the same, the nearer you will come to accomplishing what you want Another thing drop this indiscriminate use of the words, asylum and hospital I have a great deal of fault to find with our brother about that, he straddled from one side to the other, an asylum might be a place for those that are chronic Our State of Pennsylvania is just building an institution for the chronic insane, that would be an asylum, but as long as there is any hope, as long as this disease can be treated with a likelihood of cure then the term should be hospital I think the idea of having the hospitals or asylums supported from the revenue from intemperance is all nonsense Make the State realize the responsibility they have for the protection of these people and the protection of society There is no question but that some people are natural perverts just as much as they are natural horse thieves, while others acquire it One thing must be kept in mind, that is, the continued use of alcohol or any other stimulant will cause an absolute breaking down of the tissue just as much as the injury of a hand in coupling on the railroad or any other injury, it is a permanent thing and you can not get away from that You can only restore them the part that is left, you can not re-create, and the quicker we realize that it is a form of insanity and needs the same restraint and needs the same obligation on the part of the State for the same support, the nearer we will be to accomplishing what we need Take a man insane on any other subject and try to develop in him a certain degree of moral responsibility I went not long ago to a church service in an insane hospital, there were several hundred there An epileptic was seized with an attack and wanted to fight and there was an old soldier next to him who had been in the English army who became very enthusiastic and did not want to see this friend of his abused I said to him, You would not fight an old soldier, would you? and he quieted right down That will work, but you must remember that it is a disease and that the other is only an incident

Dr T D Crothers—I am glad to note such a general interest in a topic practically unknown You may theorize for a long time and not get at practical facts However, I will say that disease seems to be the only word that will explain the phenomena which appear in all these cases although it is to be deplored that we insensibly associate these vague terms, such as habit, vice and free-will in the most indefinite way with these cases Mere error confessed adds intensely to the disorder This is a new phase of neurasthenic disease that will have a very large future and we can only be investigators We should not theorize and think by so doing we have accomplished the highest good in this field

SARCOMA OF THE PIA AND BRAIN, SIMULATING BRAIN TUMOR, MONO-SPASM AND MONO-PARESIS, OPERATION, DEATH ON THE THIRD DAY

Read by title before the Section of Neurology and Medical Jurisprudence at the Forty fourth Annual Meeting of the American Medical Association

BY J T ESKRIDGE, M D
DENVER, COLO

E T P, male, aet 50, Iowa merchant, was referred to me by Dr W J Rothwell His family history is excellent His health during childhood was good, with the exception of headache, from which he suffered considerably during attendance at school After he left school his headache ceased almost entirely He denies more than occasional use of alcohol, or excess in venery During his twenty-first year he contracted a hard chancre and a few months later he lost most of the hair on his head There were no other secondaries About seven years after the initial lesion of syphilis he married His wife lived nineteen years, and during this time she had several miscarriages, none of the children reaching full fetal development The wife died a few years ago with brain trouble (probably syphilitic) Mr P seemed to continue in firstrate health until the summer of 1889, when he began to suffer from uncomfortable feelings in the back of the head These sensations at first did not amount to pain, but as time went on he had occasional attacks of headache Two years after the first appearance of the head symptoms, or early in the morning of July 8, 1891, while he was *feeling quite well, without any aura*, he was seized with a general convulsion which lasted three or four hours He remained in an unconscious condition four days The attack was not immediately preceded or followed by headache During the next two months he felt nervous, his face was flushed, and he became sleepless, languid and lost flesh He did not suffer with a distinct head pain, but he experienced an apprehensive and confused feeling

In September, 1891, he experienced a seizure, during which he did not entirely lose consciousness The attack began by a sensation which he likens to the imaginary feelings caused by one inhaling some deadly poisonous gas with a vague, indescribable taste There was no distinct odor or taste Immediately following these sensations he felt a nauseated sensation at the stomach, and a peculiarly indescribable sick feeling in throat There was an increased flow of saliva, slight drawing of the face to the left, and he seemed to himself dazed

From October, 1891, till the time of his first visit to me (June 30, 1892), there has not been a day during which he has not experienced one or more of what he calls "nervous discharges" The attacks are said to be similar in character They have all been attended by a profuse flow of saliva

He has just had an attack in my office

He shakes all over, as if suffering from a violent chill, turns pale and moans There is slight twitching of the muscles of the left side of the face, increased flow of saliva on left side, the left thumb is drawn down into the palm of the hand, with slight flexor contraction of the fingers of the hand There is no loss of consciousness Immediately after the attack, which lasts only a minute or two, there is paresis of the left hand, wrist and face muscles, with slight ptosis and wrist drop Left pupil widely dilated He describes his sensations as oppressive breathing, a sick feeling in throat, with intense chilliness, a peculiar taste, which he describes as an 'electric taste" On questioning him further to ascertain if the sick feeling is not experienced in stomach instead of throat, he affirms that the sick sensation is in throat and left side of face He says at times he feels as if the entire left side of body were on fire

Examination, July 1, 1892 —Gait is somewhat halting, the left leg being used more awkwardly than the right On closing eyes and walking backwards and forwards the disparity between the legs is more marked There are no distinct ataxic movements of legs, trunk or arm muscles Right leg muscles are much stronger than the left Dynamometer R 150, L 142 Knee jerks R nearly normal, L sluggish, but variable, and increased by reinforcing Deep reflexes of arms, increased, and nearly equal in each arm Plantar reflexes, absent on *both* sides, although stroking the plantar surfaces causes some contraction of the leg muscles Cremaster reflexes, present and about equal Lower abdominal and epigastric reflexes, absent The abdomen is very large, and covered with a thick layer of adipose tissue He has double inguinal hernia All sensory phenomena normal on right side On the left side all sensory phenomena blunted, but not abolished except in parts to be noted In left leg temperature sense is most affected Cool substances are readily recognized as such, but warm substances make no impression as such until they have been in contact with the limb a few seconds, and then the impression is much less distinct than that made by the same substances in contact with right leg Touch, pressure, posture and localizing senses seem to be slightly lessened in right leg Pain sense is normal, or nearly so On the trunk, little or no difference is recognized in the sensory phenomena of the two sides On the index of the little finger of left hand he is scarcely able to recognize two substances as such even when held three times the normal distance apart In other portions of the left hand, in left arm and face, there is only slight blunting of the sensory phenomena, less than is found in the left leg Smell, normal Taste nearly normal, except on the left side, just immediately after an attack, when it is temporarily, nearly lost Hearing R 1-12, L 1-12 Tuning fork is heard about equally distinct in each ear

Eyes R v 20-40 All fields slightly narrowed Pupil normal in size, and reacts to light and accommodation Some whitish atrophy of optic nerve Arteries nearly normal in size, veins full and slightly tortuous L v-20-200 Yesterday just after one of his attacks, the pupil was dilated to three times the size of the right, and it did not react to light or accommodation To-day the pupil is normal in size, and reacts well to accommodation, but slowly to light Fields all lessened, temporal absent Nerve very white, and shows distinct atrophy Some drooping of upper lid

He is ordered ten grains of potassium iodid thrice daily, and the dose to be increased five grains each day

July 3, the medicine has not been given regularly On the night of the fourth, he has a convulsive seizure, beginning in the left side of the face and extending throughout entire left side of the body and limbs, and three attacks of like character on the night of the fifth During these seizures he is unconscious July 6, he is taking thirty grains of potassium iodid thrice daily, and one-sixteenth of a grain of the bichlorid of mercury is given with each dose of the potassium At 6 P M I find his face of a purplish color, he is very weak, and left side of face paralyzed Dyn R 120, L 37 Saliva is constantly flowing in great quantities Speech is thick, but he has no aphasia Memory very poor During the day he has had several convulsive seizures limited to the left side of the face, but consciousness has not been lost On the seventh and eighth he has had three or four convulsive seizures in left side of face, but no disturbance of consciousness Immediately after an attack speech is impossible, and the muscles of the entire left side of the face are paralyzed and remain so for some time after the muscular twitching ceases The auræ preceding the attacks are electric, shock-like sensation in left side of face, with a flat or stale sense of taste, and great burning in left side of face On the ninth he has several somewhat similar attacks, one of which I witness, and it may thus be described he shakes himself as if feeling chilly, complains of an intense and disagreeable cold sensation running up the upper portion of spine, and almost immediately the muscles of left side of face began to twitch The left masseter seems to be the first muscle affected, then the left eye becomes convulsively closed and opened, followed by tonic closure of the eye, left side of forehead is next corrugated and drawn to left, mouth is now drawn well to left with clonic twitching of the muscles, and immediately following this, the left masseter and platysma myoides muscles begin a series of clonic convulsive movements which are kept up several minutes Finally the left trapezius and left posterior neck muscles become tonically contracted and draw the head backward and to the left The sterno-cleido mastoid muscle does not seem to be affected The left masseter and platysma muscles keep up a clonic contraction several minutes after all the other muscles cease to be affected Within a minute after the convulsive movements begin, the left hand drops, and the left wrist and hand muscles are completely paralyzed I ask him to raise his right hand and arm He does this without hesitation, but is unable to move the left hand The paralysis of the wrist and hand passes off before the platysma and masseter muscles cease to twitch During the attack there seems to be some spasmodic action of the muscles of the pharynx and larynx, most marked on left side, but affecting the muscles of the right side to some extent At the height of the seizure the right masseter muscle occasionally twitches The seizure lasts about ten minutes and during this time he is unable to open his mouth After the attack the muscles of the left side of the face are completely paralyzed and flaccid, and remain so for several minutes This side of the face is paretic between the seizures He remains speechless for several minutes When he is able to talk, he tells me that "at the commencement of the attack he experiences an electric shock, which seems to shoot through the entire left side, including arm, trunk and leg as well as the face"

July 10 He is now taking seventy grains of potassium iodid thrice daily, and has had three attacks similar to the one described, but he thinks they are less severe

July 18 He is now taking 110 grains of potassium iodid thrice daily, and has experienced no convulsive movements for three or four days, although he still has chilly sensations in back of neck three or four times daily Vision has greatly improved Right eye, v-$\frac{1}{2}$, with nearly normal fields, L v-$\frac{2}{7}$ All fields except temporal, which is lost nearly up to median line, nearly normal

Aug 1 No convulsive movements of any muscles since July 15, but he experiences what he calls "explosive cold spells" two or three times each day The cold sensation, which he says is intense, begins in left cheek, and spreads over left side of face, down spine and over left side of body There is constant tremor of the left depressor anguli oris During last two days he has had headache for an hour each day

Sept 1 Only slight change in symptoms since last record It has now been six weeks since he has had any convulsive movements The tremor in the left depressor anguli oris still continues About two or three times each day he has a "deathly" sick sensation arising from stomach, and almost instantly he experiences a cold or freezing feeling, which begins in left side of face and passes down left side of trunk He is now taking 125 grains of potassium iodid and one-twelfth of a grain of corrosive sublimate thrice daily, and seems to have but little inconvenience from these agents He has gained considerably in flesh

The diagnosis is tumor in the lower Rolandic region, and an operation has been discussed, but owing to the probable syphilitic nature of the lesion it is discouraged in favor of continuing the antisyphilitic treatment General sensibility, including tactile, temperature, pain, muscular, posture and localization senses, normal

Early in September (1892), he becomes mentally greatly depressed, is apprehensive and says that he is losing his memory There is no decided headache, but a dull, confused sensation in the head is constant There are no convulsive seizures, but he still experiences the "cold sensations" He now becomes urgent for a surgical operation, and says that he would rather be dead than endure the mental suffering that he has to undergo He fears, if something is not done to relieve him, that he will commit suicide After explaining to him the unsatisfactory results following operations for the removal of syphilitic growths of the brain, owing to the tendency of the disease to involve adjacent portions of the brain and membranes, he decides to take the risk, saying if he could not get relief he is determined to die The entire left side of face still remains paretic

On Sept 10, 1892, Dr Parkhill, after employing thorough aseptic measures, makes a trephine opening in the skull one and a half inches in diameter, with the center of the trephine over the lower extremity of the fissure of Rolando The bone is quite thick and very hard On exposing the dura its external surface seems normal There is undue tension of the membranes and no pulsation is discovered On applying the poles of a faradic battery over the exposed membrane no contraction occurs in any muscle The dura is opened and considerable watery fluid escapes Feeble pulsation of the brain is now observed The pia is opaque and greatly thickened, so that the convolutions of the brain can not be seen through it Portions of the pia are from one-quarter to one-third of an inch in thickness On applying the Keen double electrode, attached to a Flemming faradic battery, to the exposed brain substance, and using a current sufficiently strong to produce smart muscular contraction when applied to the hands, no muscular contraction takes place The trephine opening is enlarged in all directions, and the same opaque and thickened condition of the pia is observed A small incision is made into the brain substance, but nothing abnormal is found except brain substance is darker and firmer than normal

With the thickened condition of the pia it is thought best not to explore the brain farther

The patient stands the operation fairly well The parts are dressed antiseptically and he is placed in bed, carefully surrounded by warm bottles

Before the operation he made me promise that I would not let him suffer much pain after the operation, and that he should have sufficient morphin to make death painless should his case prove incurable The operation was finished about 1 p m He sleeps until 5 p m, when he awakes and complains of agonizing pain in the head He is given one-quarter of a grain of morphin hypodermically The same dose has to be repeated once or twice during the night, as he insists that his suffering is unbearable The day after the operation his pulse, which had been about 100, increases to 120, his temperature arises to 101 degrees, and he is restless and complains a great deal of pain in the head He refuses food, and it becomes necessary to force nourishment upon him Two or three hypodermic injections of morphin, one-quarter of a grain each, are necessary to quiet him during day On the morning of the second day after the operation he is evidently failing rapidly During the night he has had several convulsions limited to the left side of the face, and one which involved the whole of the left side of body As the forenoon wears on he sinks into a stupor, and by the afternoon he is profoundly comatose He died quietly at 6 p m, about fifty-three hours after the operation

Sectio cadaveris, three hours after death The brain only was examined On removing the dressing the wound was found to be free from pus, and no evidence of inflammation was present The dura was not abnormally adherent to the skull cap The veins and sinuses of the dura were distended with fluid blood, but the external and internal surfaces of this membrane presented no macroscopic pathological changes On removing the dura, the pia over the greater portion of the right frontal lobe, over the right Rolandic region and over the right temporo-sphenoidal lobe laterally, appeared opaque and thickened The greatest thickening of the pia was over the lower Rolandic region, where it was at least one-quarter of an inch in thickness The pia, over the entire surface where it was opaque and thickened, was abnormally adherent to the brain substance, and in some places, in endeavoring to detach the pia from the brain, portions of the cortex came off with the membrane On carefully sectioning the brain no gross lesions were found, except in the lower Rolandic region, especially in the lower face center, where the cortical substance seemed abnormally dark The incision into the brain substance, made during the operation, was found to be in the lower portion of the ascending frontal convolution, on a level with the lower end of the fissure of Rolando Portions of the thickened pia and of the cortical substance of the brain, immediately beneath this membrane where pathological change seemed the greatest were hardened in Muller's fluid for three months

Microscopical Appearances—"Pial membrane thickened, in places fully an eighth of an inch (one-fourth to one-third inch in fresh state)

"This thickening is due to small round cells in a delicate gliomatous tissue Blood vessel walls thickened, intima thicker than normal complete occlusion of some vessels The tissue takes the stain very readily

"*Diagnosis*—Sarcoma (small round-celled) Glioma Tumor mass in membrane

"Sections show a delicate capsule of connective tissue, covered by endothelial cells From the capsule delicate bands of connective tissue run into the mass, forming lobules which are in some parts quite large In other parts of the tumor no lobular arrangement is found, but the tiny threads of connective tissue run in and about the cells

"The cells are small, round and nucleated

"In a few places near the center of the growth the connective tissue is somewhat condensed, forming rings In these rings of connective tissue are found large, round, yellowish masses, typical of psammoma Under a high power (×450) no cellular arrangement can be made out, but a center with fibrillated rings about it can be seen Many of the spaces in the center of the tumor contain nothing, but obviously they contained before section more of this psammomatous material

"In and around the mass of small round cells are large, round, well stained plates of material, the nature of which is doubtful No cell structure can be made out They may represent the first stage of the psammomatous change

"*Diagnosis of tumor mass*—Sarcoma of the small round cell variety, with gliomatous tissue and psammomatous change

"*Brain*—Every section shows round celled infiltration, extending through the gray matter into the white This infiltration is especially marked along the line of the blood vessels The stroma of gliomatous tissue is well seen

"*Diagnosis*—Sarcoma (glioma)

"E R Axtell,
May 10, 1893 "A S Lobingier"

A few points in connection with the clinical history of the case and the results of the autopsy and microscopical examination are worthy of comment

If a person who is suffering from symptoms of tumor of the brain gives a history of syphilis, we feel justified in looking upon the growth as being of syphilitic origin, further, should a trial with anti-syphilitic agents result in great improvement, we feel almost certain that the tumor is syphilitic in nature We have long since learned in the treatment of growths of the brain that if improvement does not follow the use of potassium iodid and mercury, it is no proof that the growth is not syphilitic In the case under discussion there was a distinct history of syphilitic infection, and on placing the patient on large doses of potassium iodid in connection with mercury decided improvement followed, so that for several weeks prior to the operation no convulsive movements of the voluntary muscles occurred

The auræ that preceded each attack were limited to the left side, and mostly to the parts on this side affected by the pial lesion on the opposite side of the brain The aura connected with the sense of taste was one of the first manifested in the history of the case, and may be accounted for by the pial thickening extending over a portion of the right temporo-sphenoidal lobe

Is it possible to determine in a case of tumor of the cortical substance of the brain whether the pia is extensively involved? When the pia is infiltrated with the growth one would expect to find severe and persistent headache, but in the case just reported headache was rarely present, and it was never severe The most important diagnostic symptom, it seems to me, pointing to pial involvement is the presence of two or more auræ occurring with or without convulsive movements Multiple auræ, occurring regularly and at about the same time, are suggestive of extensive cortical irritation, involving numerous brain centers, a condition that is probably rarely met with in tumors limited to the brain substance It is not probable that tumors of the pia can be removed with safety to the patient, on account of the extensive infiltration of the membrane in such cases

There are several other features recorded in connection with the case reported in this paper worthy of discussion, but I will at present only refer to one During the irritative stage of the growth before paresis became permanent, disturbances in sensory phenomena were well marked, most affecting heat, next tactile, and least of all, pain sense The sensory impairment was always most distinct immediately after an attack As infiltration of the cortical centers for the face and arm progressed, and paresis of the face became well marked, all sensory phenomena in these parts became normal, except for a variable period following an attack One explanation of this condition might be found in attributing to the cortical substance an inhibitory influence over the "sensory centers," whose inhibition is lost when paresis or paralysis results from destruction of the cortex Another interpretation of the phenomena may be found in supposing that other portions of the brain cortex may perform the functions of disabled areas

---

CEREBELLUM CYST—ANTE-MORTEM DIAGNOSIS

Read in the Section of Neurology and Medical Jurisprudence, at the Forty fourth Annual Meeting of the American Medical Association

BY WILLIAM C KRAUSE, M D
BUFFALO, N Y

For the history of this case and the pleasure of having made the observation, I am indebted to my friend, Dr Linus T McAdam of Buffalo, N Y

Name, Jacob M , age, 36 years, height, five feet seven inches, weight, 170 pounds, complexion fair, constitution robust, well developed Antecedents, nothing of particular note was elicited, family history good

Early History—The patient passed through infancy and adolescence, without any serious illness, never contracted syphilis or gonorrhea Some years ago he suffered a slight attack of insolation from which, however, he seemed to have fully recovered

Present History—On October 23, 1892, the patient consulted Dr McAdam for pain in back of the head, dizziness, nausea, peculiar revolving sensations in his head and on standing or while walking an inclination to be drawn backward So strong were these last sensations that while the patient was in bed he would be compelled to turn on his right side, his head deep in the pillow, or while working in a stooped position he would suddenly fall backward, and on several occasions received quite severe knocks on his head Along with these symptoms there coexisted a sub-normal temperature, slow pulse, furred tongue, loss of appetite, sallow complexion, discoloration of the conjunctivæ and constipation The patient was administered hepatic stimulants, but without obtaining any alleviation of the distressing symptoms A few days after this first visit he again consulted Dr McAdam and complained of great thirst and gave a history of polyuria On examination the urine was found to contain sugar in abundance and on measuring the urine it was found that he passed sixty to seventy ounces daily About this time (Nov 7, 1892), he experienced considerable difficulty in walking and was obliged to discontinue all work and remain at home With assistance he was still able to walk about the house but his gait was unsteady, staggering, with a marked tendency to fall backward and to the right

With the exception of the glycosuria and polyuria which subsided under careful treatment, the remaining symptoms gradually became more and more severe and a consultation was held The disease was diagnosed as of cranial origin but no definite diagnosis was reached All methods of treatment proving unavailing and desirous of further counsel the writer was called to see the case on January 17, 1893, with the family physician, Dr McAdam

The patient was found lying upon a couch complaining of intense occipital pains radiating toward the vertex On sitting up he felt dizzy, nauseated and as if his head were being pulled backward On attempting to walk his gait was staggering, with a desire to fall to the right and backward

Psyche—His mind seemed to be clear and unaffected, sleep, fair

Motility—The strength of the muscles of the extremities was diminished but no more than the inactivity to which he was subjected would warrant

Tendon Reflexes—The patellar tendon reflexes were slightly exaggerated Other superficial and deep reflexes were normal

Sensation—There existed no disturbances of the sensory nerves, trophic and vaso-motor disturbances were likewise wanting

Special Senses—Unfortunately the fundus of the eye was not examined, due perhaps to the fact that no ophthalmoscope was present An ophthalmoscopic examination was, however, promised but failed eventually to materialize No abnormalities whatever of the special senses were discernible

To me it seemed clear that we had to deal with some cerebellar neoplasm, but what its nature or origin I could not say The characteristic symptoms of cranial tumor, such as intense cranial pain, obstinate vomiting, vertigo, coupled with symptoms which we are wont to denominate cerebellar, as staggering ataxic gait, inclination to fall backward, occipital tenderness, etc , warranted the diagnosis arrived at

Not receiving the desired promise of speedy and certain recovery, the patient sought other advice, and the history or the course of the disease was unfortunately interrupted On the evening of March 15, Dr McAdam was hastily called and arrived in time to see the fatal termination Inquiry elicited the fact that for two or three weeks previous the patient developed a slight fever with occasional chills No convulsions were noticed at any time

An autopsy was made the following day by the writer, assisted by Dr McAdam, with the following results the calvarium was rather thick, dura somewhat adherent The pia was clear, vessels not markedly injected, Pacchionian bodies small and sparse The convexity of the brain appeared healthy, the convolutions were not flattened and the fissures were of usual depth The cerebrum was removed, beginning cephalad, the basilar structures carefully severed, and on cutting through the right side of the tentorium cerebelli, a clear amber-colored fluid flowed into the cerebral cavity The cerebellum was carefully removed, and in the inferior occipital fossæ was found about one to one and one-half ounces of amber-colored fluid On closer examination, the right lobe of the cerebellum was found to be flattened, boggy and considerably smaller than the left lobe This condition was quickly explained by the presence of a large cavity in the right lobe, the walls of which had collapsed and the fluid had escaped during removal of the cerebellum The entire right lobe appeared to have been undermined and virtually was nothing more than the walls of the cyst During the dissection and examination of the cerebellum the undertaker thoughtfully and thoughtlessly sponged the cranial cavity, thus depriving us of any of the cystic fluid for a more careful microscopic examination It is therefore impossible to say just what the character of the cyst was, whether it was the result of hydatid disease, or of inflammatory or hemorrhagic origin

My object in publishing the details of this case is not because it is an extraordinary one, or because the diagnosis was verified by the autopsy, but rather to prove that the symptom-complex of cerebellar disease is distinct enough to permit of more radical surgical procedure The writer is not aware that much has been done in this direction, and certainly in this case much might have been gained through surgical interference

The tendency of the patient to fall to the right and backward, and the discovery of the cyst in the right cerebellar lobe, would impress one with the idea of connection between disease and symptoms, both pertaining to the same side Whether this law holds true in every case, I do not pretend to say Another interesting fact was the temporary glycosuria and polyuria, its sudden appearance and its more sudden demise Whether this was the result of pressure, or whether it was merely accidental, must be left unanswered, although I believe the former to be the more plausible

382 Virginia Street

SPECIAL INFLUENCES OF ALCOHOL ON THE BODY

Read in the Section of Neurology and Medical Jurisprudence, at the Forty fourth Annual Meeting of the American Medical Association

BY T L WRIGHT, M D
BELLEFONTAINE, O

In discussing the nature of inebriety, and the magnitude of its influence on mankind, it will be necessary to observe the effects of alcohol upon the physical body, upon the mind and upon the moral attributes

And first, let us consider some of the effects of alcohol upon the material organism

The influences of alcohol upon the human body are of a nature so intricate, so distracting and often so apparently inconsistent with each other, that it is difficult to classify them in a clear and satisfactory manner

These influences might be arranged into groups representing on the one hand, drunkenness, its relations and phenomena, and on the other representing physical degenerations, with their various connections and dependencies Perhaps as comprehensive a division of the subject as any would be as follows

1 The effects of alcohol upon the nerves,
2 Upon the blood, and
3 Upon the physical integrity of essential organs and tissues

This classification will no doubt prove to be defective, and the several lines and boundaries of distinction between its component parts will be, in many places obscure, or possibly lost altogether

1 In speaking of the effects of alcohol upon the nerves, it will be proper to advert to the impression of that agent upon the muscular sense Alcohol is carried everywhere by the circulation, and in drunkenness the functions of the muscular system are hampered and deranged This fact arises in a great measure from the peculiar property of alcohol, which imposes a degree of paralysis upon the nervous system, in all its several parts and qualities There is loss of muscular power, and also disorder in the functions of muscular coordination Movements are out of proper relationship with each other Partial paralysis from causes other than alcoholic, present when of wide application, similar appearances and defects Take a case of general paralysis of the insane—partial, however, in degree "This disorder," says Dr Tuke, "is marked by loss of coordinating power over the muscles, especially those of speech and locomotion Precise coordination of movement, such as is necessary for writing, sewing, playing upon a musical instrument, and like acquired and automatic acts, is much impaired, or quite lost" This is in every particular an exact description of the muscular disabilities of a person who is drunk The movements assumed in walking will betray the condition of a person, even when slightly intoxicated. The feet are not raised fairly and clear of the ground, and there is frequent scraping or slipping of the shoes upon the pavement

It has been said that "the commencement of intoxication was flushing of the face, indicating that the cervical sympathetic was becoming paralyzed"[1] This is probably true in most instances But especially in neurotic periodical drinkers, there is a remarkable deviation from this rule When the dipsomaniac, after a season of rest begins to swallow large quantities of strong liquors, "the vaso-motor centers in the bulb and cord" do certainly show indications of the toxic action of alcohol But they do not consist of flushing the face through paralysis The exhibition is rather that of spasm and rigidity, not only of the muscular system at large, but of the capillary blood vessels also,—their caliber being apparently diminished

The beginning of a season of drunkenness in the neurotic is commonly marked by paleness of the face. The features are sharp and contracted The nose is pointed, cold and colorless The eyes are *not* rolling and without expression, as in ordinary drunkenness On the contrary they are steady, although quick in movement They also are bright and penetrating The speech is *not* inarticulate, stammering and disconnected, but words are clear cut, perhaps "clipt," and evidently of spasmodic utterance The muscular movements although somewhat constrained are not staggering, incoordinate and uncontrollable In fact, while large quantities of alcohol may have been consumed, the appearances of intoxication which are the outcome of paralysis, are not always speedily developed The paralytic stage of drunkenness may not appear for many hours in the neurotic drinker, though of course that is not the rule The primary effect of alcohol upon the neurotic inebriate may be that of shock This alcoholic condition is not without its important bearings upon the question of inebriate responsibility, for as long as it continues there is danger of violent and unreasonable outbursts of rage and hate The consequences may be tragical, for there is an unnatural exaltation, both in the power and disposition to wreak vengeance for fancied wrongs Dipsomania has been described as an insane exhibition among a group of insane exhibitions—all symptoms of a central disease "The opinion which would make of dipsomania a separate disease, can not stand against a complete study of the facts It is a detached page in the history of the patient's disease which can not be understood if studied by itself"[2] Another authority says "It seems to me more correct to regard dipsomania as a symptom belonging to a general disease"[3]

The action of alcohol upon certain peripheral nerves marks it as a poison A long and persistent course of drinking is liable to produce neuritis in one or more localities in the organism This may prove destructive to the integrity and life of the special nerves affected Herein alcohol acts in a manner similar to other tissue poisons—similar for instance, to lead and arsenic The plantar nerve, the popliteal, the musculo spiral, the tibialis anterius, are some among the nerves for which the alcoholic poison displays its peculiar affinity When the drinker loudly complains of pains in his legs and feet, and talks of rheumatism and neuralgia, the probability is that he is suffering from alcoholic neuritis in his lower limbs

---

[1] Buzzard [2] Magnan [3] M Foville

Among the larger and more prominent nerves which may come under the toxic influence of alcohol, are the phrenic nerve and the pneumogastric

To the evil influence of alcohol upon the vagus, is attributed serious irregularities in the heart's action Chronic pulmonary catarrh also, with paralysis and stagnation in the smaller and more remote bronchial tubes, may be referred to a kindred origin It is believed moreover, that the fatality of pneumonia so remarkable in the drunkard, is largely owing to the injury inflicted upon the eighth pair of nerves by the alcoholic poison

The first indication of alcoholic neuritis is change of sensibility—there frequently being severe pain But the morbid feelings may vary It is possible that they may become sources of troublesome hallucinations and of true insanity

The destructive effects of the alcoholic poison in neuritis may be seen in the condition of the nerve after the disease has run its course One description declares "The lesion of the nerves consisted of granular degeneration of the myelin, then partial removal of the products, causing varicosity of the nerve fiber, and lastly, complete disappearance of the degenerative debris, with collapse of the sheath "[4]

The alcohol of wine it is said, does not produce the nervous degenerations herein described Since the discovery of distillation, and the enormous consumption of distilled spirits during the last two hundred years, wine has lost the position of respectability once accorded to it by many of the ancient writers It is now looked upon with suspicion as a substance capable of leading the unwary into habits of vice and profligacy that were impossible before the discovery and use of the concentrated alcohols of modern days

The disturbing influence of the paralysis of alcohol upon the normal display of the inhibitory nerve functions is generally recognized Still, the facts and evidence on that subject are something obscure and incomplete, and they will not justify any labored effort towards detailed and specific description The paralyzing (anæsthetic) influence of alcohol upon common sensation appears to have been known in the most remote periods of time This is, in many circumstances exceedingly seductive, and yet, in its effects upon the mental and moral attributes it is often of very great injury

2 In discussing the several divisions of our subject, a very brief synopsis of the more obvious *effects of alcohol upon the blood* is all that can now be offered in that connection

A striking effect of alcohol upon the circulating fluid, is the production of changes in the appearance of its red corpuscles They suffer shrinkage, and often a material change of form Their color too, is affected, and they become darker under the alcoholic influence When alcohol is mixed with blood, the red portion of the corpuscle may escape from that body altogether The globules are deprived of their power to perform their functions completely and physiologically They are incapable of absorbing and distributing the amount of oxygen necessary for the healthful supply of the bodily structure In other words, "the blood globules when impregnated with the toxic spirit, have lost the property of transforming all their hemaglobin into oxy-hemaglobin "[5] Alcohol displays undoubted power over the white globules also, but the insignificance of its effects are not so readily demonstrable upon them as upon the red bodies

One of the consequences of the toxic influence of alcohol upon the red corpuscles is the undue collection of carbonic acid within the organism The retention of a portion of this acid is the subject of various hypotheses and explanations It is said, for example, that a part of the oxygen inspired combines with free alcohol in the circulation, converting a portion of it into acetic acid[6] This leaves an insufficiency of oxygen to properly change the character of the blood corpuscles from venous to arterial The theory, however, does not account for the shrinkage, and other structural changes which occur in the red globules when brought strongly under the influence of alcohol It is not therefore, simply a matter of defective balance, or of deficiency on one side or the other, but the influence of alcohol upon the red blood corpuscles appears to be really that of a *poison*

The harmful retention of carbonic acid in the human body when it is under the alcoholic influence, depends upon more causes than one The operations of alcohol are always complex The elimination of carbonic acid by the lungs is impeded by overcrowding the capacity of those organs The enforced exhalation of alcoholic vapor interferes with the normal ability of the lungs to expel the poisonous acid The toxic qualities of the retained gas produce general uneasiness and also special distress The headache which follows alcoholic intoxication is peculiarly violent, for the blood vessels of the brain are loaded with effete and noxious material But a very serious complication that may arise from the influence of alcohol, consists of the accumulation of large quantities of fat in different parts of the organism This may be owing to the fact that the constituent elements of alcohol, as well as of the waste and effete material in the blood, may undergo certain slight changes which result in the formation of fat In the chronic inebriate, fatty degenerations of the liver, heart, and elsewhere, are liable to appear, and these in many ways provoke functional irregularities

A deficiency of oxygen in the system may favor the establishment of the gouty or the rheumatic diathesis "There is no possible chance of relief to those who are inclined to the lithic acid diathesis, if they arrest oxydation by the use of stimulants and narcotics Arrest that oxydation by the use of alcohol, and you add to the amount of unhealthy waste which has to be removed Lithic acid can only be removed by oxydation "[7]

Intimately associated with the deficiency of oxygen in the blood of the drunkard, is the low temperature of his body While alcoholic paralysis exerts—no doubt by its inhibitory force—an influence in the reduction of animal temperature, the incapacity of the red globule to absorb oxygen and to eliminate carbonic acid, exercises an unquestionable tendency in the same direction In profound drunkenness heat has been known to fall as much as 8° F , and it has been shown that in some instances the normal temperature has not been restored for three days[8] The complaints of the drunkard himself (upon emerging from his condition of anæsthesia) indicate very uncomfortable sensations of cold When the inebriate begins to arouse from his torpor and stupidity, he is invariably chilly and shivering He draws towards the fire, or hastens to protect himself with an abundance of bed clothing

It appears to be a fact that alcohol may reduce temperature through the force of its paralyzing and anæsthetic properties It is a question with some whether the reduction of temperature through the establishment of toxic and pathological states of the blood is not probably as injurious in one direction as it may be beneficial in another In the high temperature and nervous irritation of typhoid fever, the effects of a topical application of alcohol (diluted) are sometimes of great value The application should be quite extensive over the abdomen The local anæsthesia will not only quiet superficial nervous excitement, but it apparently extends to the subjacent tissues Under this treatment the morbid temperature will materially abate Diluted alcohol may also be applied to the aching head and to the burning feet and hands This procedure may accomplish valuable results without interfering with the normal functions of the blood globules Should a degree of intoxication be induced, it may be remembered that abstractedly, intoxication may exist without a poisonous impression affecting the essential constituents of the blood, which fact in the reduction of morbid temperature is a point of no small importance

In the hard drinker a portion of the alcohol finds its way into the blood and remains uncombined It has a powerful affinity for water It is speedily found in every part of the bodily structure Of course much of it enters the system through the portal vein and the right side of the heart But alcohol also seems to *diffuse* itself throughout the organism directly It is in the breath immediately Emesis shows that it remains in the stomach for a very brief season indeed, while giddiness, confusion of thought and movement—in short, *drunkenness* shows that alcohol mounts at once to the brain

When there is a certain excess of alcohol in the system, the movements of elimination may proceed with a good deal of vigor But when the excess is removed, there remains a portion apparently in a kind of static condition At all events purgatives, diuretics, diaphoretics, the lungs themselves, appear to exercise a limited power only in its final disposition It is not unlikely that certain structural degenerations may be connected with this state of facts, and especially fatty accumulations and other hyperplasias

Delirium tremens is indicative of a brain saturated with alcohol The natural wetness of the brain, containing as it does a very large proportion of water, probably invites the presence of alcohol more urgently than is the case with many other organs However that may be, it is an opinion widely held that in delirium tremens there is a direct poisoning of the system at large, and especially of brain tissue, with alcohol pure and unchanged

3 Alcohol has been called the "genius of degeneration" Some of the prominent changes in the structure of important organs, when the outcome of alcoholic impression, are indeed of great interest, and a brief notice of them will not be unprofitable And first of the heart

"The heart of the inebriate at first is made tense and full by alcohol, but is easily depressed Under this depression, however, the circulation becomes of a character that has been termed *rotten* The continued use of alcohol tends to permanent enlargement and dilatation of the heart, with stretching of the valves—especially the semilunars There is also distension of the arterial system throughout, leading to loss of elasticity There may be a feeble, large heart, dilated arteries, enlarged and bulging veins. The corporeal mechanism of the heart is, in fact, changed altogether Such a condition of the circulation would necessarily occasion much uncertainty both of the mental and bodily functions"[9]

Again In the fatty degenerations common in alcoholic inebriates, both in the light daily drinker and in the habitual drunkard, the heart is frequently implicated The substance of the heart is permeated with fat globules, and its strength and endurance are impaired

It is believed, moreover, that the structure of the heart may be seriously affected in consequence of alcoholic degeneration of the eighth pair of nerves[10] The muscular tissue of the heart, it is supposed, may undergo shrinkage and atrophy from this cause, in a manner similar to the shrinkage of the leg from the toxic influence of alcohol upon the nerves there distributed

The heart may also become exhausted through its too frequent and irritable pulsations in the daily drinker The physiological rest between the heart beats is not permitted to take place In this as well as in the several degenerations already named, there is incapacity of function, and heart prostration is, to some degree greater or less, always impending

Degenerations due to alcohol very often affect the liver They present a variety of aspects Fatty degeneration is the one most commonly met with The liver is enlarged in this affection, and it is loaded throughout its whole extent with fat

Another prominent form of hepatic degeneration is cirrhosis, producing the so-called "gin liver" The gland presents a contracted and solidified appearance with a rough surface, from which it has been also designated the "hobnail liver," "nutmeg liver," etc.

The kidneys may likewise become the seats of fatty deposit, and they too are liable to undergo the characteristic changes in structure indicative of fibroid degeneration

A remarkable property of alcohol is sometimes displayed in its influence upon the connective tissue of the organism There may be hyperplasia and considerable enlargement of this substance This is not simple hypertrophy, however It is a consequence of the toxic impression of alcohol The tissue implicated in this alcoholic hyperplasia is invested with properties quite different from the fibrous tissue in its physiological state After a season of enlargement, it takes on a process of contraction This movement is so marked that entire organs are misshapen, indurated and radically impaired in function The fibers of the shrinking mass enclose the substance of the liver, or kidneys, or other organs in their embrace, and the outcome is the gin liver, the kidney with interstitial nephritis, and the like disasters elsewhere These phenomena are the direct results of the poisonous qualities of alcohol—there is nothing normal nor physiological about them

---

[8] Dr B W Richardson

[9] B W Richardson

[10] Dr Sharkey

The drunkard's brain has an abnormal amount of serum in it This is owing, in part at least, to atrophy and it "resembles in this particular the brain of the senile condition—of old age The convolutions look small, the sulci deep, and in most cases the pia mater is easily removed"

The membranes of the inebriate brain, including the dura mater, are *often thickened, and they may* display other indications of organic disease "The structural lesions of the brain show patches of sclerosis and other evidences of injury that are due to alcohol, and, in fact, these may resemble the changes that are found in the brains of paretics" It is true, however, that these degenerations are absent from a very large proportion of inebriate brains

The relations of alcohol to paralytic dementia have been the subject of much controversy There is one point, however, upon which all seem to agree in regard to that question, namely Alcohol may become an exciting cause in the production of paralytic dementia in certain constitutions, as, for instance, when great mental labor has been forced upon a brain incapable of sustaining the strain necessary for its performance The principle has been expressed thus (the alcoholic habit being present) "Enforced functional strain with incapacity to bear it, or disproportion between functional activity and power of resistance, may end in paralytic dementia" To this extent, at least, alcohol may be classed among the causes of paresis, and of the physical degenerations found in the brains of the paralytic insane

Enough has now been said of the effects of alcohol upon the physical organism to indicate the nature and extent of their application It is comparatively easy to investigate the bearings of the facts presented upon the mind and upon the moral constitution of the inebriate

---

ON THE CARE OF EPILEPTICS

Read before the Section of Neurology and Medical Jurisprudence at the Forty fourth Annual Meeting of the American Medical Association

BY FREDERICK PETERSON, M D

NEW YORK CITY

Professor of Nervous Diseases in the University of Vermont, Instructor in Nervous and Mental Diseases at the College of Physicians and Surgeons, New York Attending Physician to the New York Hospital for Epileptics Pathologist to the New York City Asylum for the Insane

The care of epileptics really includes their medical treatment as well as all other kinds of help extended to them But medical care, such as it is, has been given to them for some thousands of years, and yet without adding much to the happiness of individuals under treatment, or accumulating much evidence of positive value concerning medication in epilepsy Our results have been, indeed, almost valueless, for, with all our dosing with bromids, borax, belladonna and so on through the alphabetical index of the Pharmacopœia it is extremely doubtful if in ordinary practice, 1 per cent of the cases of idiopathic epilepsy are cured Besides the practical incurability and hopelessness of the disease, its victims have suffered untold sorrows in the way of negligence and ill-treatment at the hands of the communities in which they live

It is a peculiarity of this disease that the seizures may be momentary or may last for a few minutes only, recurring sometimes frequently, sometimes daily and sometimes months apart, thus robbing the sufferers of their consciousness and faculties for brief periods of time at long or short intervals Between the attacks they may be as rational and as well qualified for all the vocations, duties and social privileges of life as any other human being

These facts do not concern only a few members of the community Epilepsy is a widespread disorder *and it has been calculated that one person in five* hundred is thus afflicted Thus there would be in the neighborhood of one hundred and thirty thousand such unfortunates in the United States alone, and over twelve thousand in the State of New York Even supposing this percentage to be exaggerated to a very great extent and that the actual ratio were one to one thousand, the number of epileptics would still be enormous and would constitute a large part of our defective classes

Outside of the efforts, thus far comparatively futile, of physicians to alleviate their purely physical infirmities, and to reduce the number and severity of the attacks, nothing has been done until late years to provide for their mental development and to meet the peculiar conditions of life which they are called upon to endure Thus, no general hospital will receive such cases for treatment, because of the incurable and unpleasant nature of their malady While much of the time thoroughly capable of acquiring an education, they are debarred for obvious reasons from the schools, the churches are closed to them, very few care to employ epileptics in shops, stores or offices or are willing to teach them trades Few epileptics are at liberty to enjoy the companionship of their fellows, who are rather inclined to shun their unfortunate brethren Thus, every avenue for mental or moral development, for occupation, for association with the rest of mankind is closed to them They are even burdensome to their families It is little wonder, then, that many of them grow up dull and ignorant, intellectually feeble, morally depraved, irritable in temper with tendencies to retrogression and degeneration rather than to advance A few of them become insane and are sent to insane asylums Others are not insane, but, ill adapted for existence under such miserable conditions, drift to the only homes offered to them, the almshouses The almshouse and the asylum are the only refuge when abandoned by their friends In the State of New York, for instance, where there are twelve thousand epileptics, some four hundred or more are in insane asylums, and some six hundred in the county poorhouses The rest of them are scattered throughout the State in their own families, among the rich and the poor, in ratio to the population and to the relative proportion of these classes Many are so slightly affected that they are able in spite of their seizures to pursue some of the ordinary vocations of life Thus, I know personally of a doctor, clergyman, several bookkeepers, a bank president, a stockbroker, several clerks, some dressmakers shoemakers, masons and a telegraph operator, who are epileptics, and yet able to carry on useful pursuits, albeit under adverse conditions To all of us are familiar certain well-known historical or literary characters in whom epilepsy failed to restrict the development of their genius, such as Cæsar, Napoleon, Moliere, Petrarch, Dostojewsky and others

It would seem, therefore, from the above facts that, although there is such a thing as epileptic insanity, the proportion of insane epileptics to sane epileptics is very small, much less than 10 per cent, taken at the utmost, and that this ratio may be reduced by affording these unfortunates such opportunities for mental and moral development as are enjoyed by other and more happily situated citizens, and not only may the percentage be reduced, but the comfort and prosperity of all epileptics be increased by proper provision on the part of the State or through private channels such as institutions of a peculiar character adapted to their peculiar needs A large public hospital is very far from meeting their requirements, for as has already been shown, medicinal treatment is uncertain and unpromising Insane asylums should receive but very few, and almshouses none at all What is demanded is an institution on the community or village plan, where medical treatment (such as it is) may be given to every member and where every sort of education, employment and social privilege commensurate with his needs and conditions may be extended to every beneficiary

The colony system only can attain this object A colony for epileptics is not an impracticable scheme proposed by visionaries It is already an accomplished fact The Bethel epileptic colony at Bielefeld in the province of West Thalia, near Hanover, Germany, was founded by Pastor von Bodelschwingh, over twenty-five years ago He purchased a small farm with one house, and with four epileptics as a beginning established a charity which for nobility of conception and success in its results has nowhere an equal It seemed to its beneficent founder, feasible to create a refuge where sufferers might be cured if curable, might have a home if recovery were impossible, might learn trades and the great majority become educated, useful and industrious citizens From that small beginning there has been a gradual evolution of his idea, until now there are over one thousand epileptics, resident in some sixty or more houses, scattered irregularly but picturesquely over a large farm Every one who visits this unique colony is deeply impressed with the happiness, contentment and prosperity everywhere apparent among the inhabitants of this little epileptic world He sees that it is no longer an experiment and the previously unanswerable objections to such aggregations are by its success answered and silenced At the time of my visit to Bielefeld, in 1886, there were but eight hundred and twenty-five epileptic patients The employments were numerous and varied A school provided instruction for some one hundred and fifty pupils of both sexes All branches were taught The dairy and the farm and garden occupied the attention of the greatest number of the patients, especially as a large trade in vegetable and flower seeds was carried on by the colony

Among the shops for epileptic workmen were those for cabinetmakers, painters, varnishers, printers, bookbinders, blacksmiths and foundrymen, tailors and shoemakers, and among the stores, were a grocery, pharmacy, bookstore and a seedstore The carpenters aided in the building and furnishing of new houses Plans and drawings for new buildings were made in the architects room Epileptics were employed in all the departments of industry relating to building Books were printed and bound and sold here, especially works for moral and religious instruction The illumination of mottoes for hospital wards and schoolrooms, and the coloring of picture cards were features of the work performed, washing, cooking, knitting, sewing and fancy work employed many A bureau had been established for the collection and sale of museum objects, such as antiquities, articles of ethnographic and historic interest, autographs of distinguished people, coins, stamps, bronzes, gems, engravings, etc, and specimens from the animal, vegetable and mineral kingdoms For men alone there were over thirty different callings

The houses presented great diversity of architecture and position They were well separated, generally enclosed in individual gardens, surrounded by fences, hedges and many trees, and altogether exhibited the homelikeness of a country village with little or nothing to suggest the restraints or discomforts of large institutions There was one small cottage set aside for such cases as should be mildly insane, but bad cases of actual insanity were sent to insane asylums Everything had been thought out carefully for the perfect evolution of this little social world, not only the multiplicity and details of occupations which would give each member of the community his choice of callings, but even the avocations, games, amusements and entertainments that might tend to divert his mind from the contemplation of his misfortune And since my visit the colony has continued to expand, to develop new and valuable features and to confer its blessings upon large numbers of persons afflicted with this disease

Taking Bielefeld as a model, nine other similar epileptic colonies have been established in Germany, one in Zurich, in Switzerland, and one in Holland Most of these are not conducted by the State, but are under the jurisdiction of private or church charities None of them are altogether self-supporting but some of them approach very near to it

It should be stated that before the founding of the Bethel colony at Bielefeld, a somewhat similar institution, though on a much smaller scale, was begun in France in the village called La Force, near Lyons Over forty years ago a noble clergyman named John Bost established this institution and it is in a flourishing state, doing a vast amount of good and redounding to the credit of its creative genius

It has been found in all of these colonies that no harm is done by bringing epileptics into contact with each other They feel on an equality with their fellows in such a place, losing that sense of isolation and singularity which they can not but observe in the ordinary world as separating them from the rest of mankind They enjoy caring for each other and being kind and helpful to their fellow sufferers It has been noted, too, that the number of seizures almost always diminishes upon entering the new and hopeful and encouraging life begotten by the busy community

Within two or three years, interest has been awakened in other countries in the matter of provision for epileptics, notably so in America and England, where their peculiarly sad condition had neither been noted nor considered In 1890 Ohio took steps toward the establishment of an institution for epileptics, a commission, consisting of Messrs J L Vance, C C Waite and one other having been appointed by Governor Campbell, pursuant to an act of the

Legislature to select a site and prepare plans for the purpose Of various sites examined, one at Gallipolis seemed best adapted for the project and here a tract of one hundred acres was presented to the State by the citizens for the institution To the writer, who was consulted upon the subject of site and plans, this seemed to be the best location offered, for, although an insufficient space for a large institution, there was plenty of land adjacent which could be subsequently added to the original tract Contrary to the advice of the writer the architect felt obliged, probably owing to the demand of the community of Gallipolis for an institution of striking proportions, to group the buildings on a symmetrical plan, such as is frequently carried out in the public establishments for the insane The Ohio epileptic hospital is built on the pavilion or cottage plan, a large number of these being grouped about the center or administration building It will, therefore, not meet in this important particular the requirements of a colony for epileptics, although in respect to provisions for school buildings, shops and the like, an effort has been made to fit the institution for the particular kind of care needed by this class The name of the institution for epileptics in Ohio is also unfortunately chosen, for it is called, "The Asylum for Epileptics and Epileptic Insane" The corner stone was laid with appropriate ceremonies November 12, 1891, an interesting address and historical review being given by General Roeliff Brinkerhoff, president of the Ohio State Board of Charities Three of the buildings were completed and made ready for occupancy in 1892 and nine additional cottages are now in course of construction, the last Legislature having made a liberal grant for the purpose In California, detached buildings are being erected upon the grounds of the California Home for Feeble Minded in Sonoma County, with the view of accommodating the epileptics dependent upon the State for pleasant quarters

Active measures are being carried out also in Massachusetts, Pennsylvania, Wisconsin and Illinois for the purpose of securing State care and separate provision for the same class of unfortunates

Next to Ohio, the State of New York has manifested the most interest in her epileptic dependants, and in the winter session of 1891-92 a law was passed by the Legislature making the State Board of Charities a Commission, to select a site and prepare plans for an institution for epileptics The law was authoritative in requiring the tract of land secured for the purpose to be four hundred acres or more in extent, and the whole scheme of buildings to be arranged on the colony or village plan A committee of the State Board of Charities, consisting of Messrs Oscar Craig, William P Letchworth, and Peter Walrath, has been busy all of the past summer and autumn (1892) in examining a large number of localities which they were invited to inspect by the officers of various counties In their report made to their Legislature on Wednesday, January 11, 1893, the State Board of Charities unanimously recommended for the proposed colony a site in Livingston County, consisting of over eighteen hundred acres, the property of the Shakers, now known as the Sonyea Society of United Christian Believers The Shakers have dwindled in numbers to such an extent that they decided to give up this colony and rejoin the mother colony near Watervliet, N Y The land is beautifully situated in the Genesee Valley, near the town of Mt Morris and in one of the finest regions of the State It is exactly fitted to meet the wants of a model colony for epileptics It is traversed by two streams One of these, the Cashauqua Creek, flows through the middle of the land in a deep gorge, with a fall of one hundred feet This gorge and creek give immense advantage for the complete separation of the sexes in free colony life The supply of water is abundant and the conditions for good sewerage perfect and adequate in every respect The Western New York and Pennsylvania railroad runs through the land and two great trunk lines, the Erie railway and the Delaware and Lackawanna railroad are within a mile of the proposed colony The soil is exceedingly fertile and well adapted for all manner of agriculture, horticulture, the production of berries and fruits for canning industries and the raising of garden produce and seeds of all kinds It has some stone and brick-clay, which will prove useful in the development of certain forms of outdoor employments It already contains scattered buildings for the accommodation of three hundred patients

The law which was introduced at the last session of the New York Legislature embodied provisions for the purchase of this tract of land and also for the methods of management, government and admission of patients to the colony As some of these may be useful to those interested in the establishment of similar institutions, a few of the chief points will be mentioned here

The name of the institution is "The Sonyea Colony" Thus, any direct reference to its object is avoided in the title The word "Sonyea," is an old Indian word, meaning sunshine, and is historical in that this point was once the site of an ancient Indian village of the same name For the present all insane epileptics are to be excluded, but probably ultimately there will be some building for the insane, especially for such as become mentally deranged temporarily while residents of the colony, since their removal from the happy influences of the community system to an asylum for the insane would be very depressing and tend to retard rather than promote their recovery

There will be nine managers appointed by the Governor, two of whom are to be women and two to be physicians They are to represent the eight judicial districts of the State of New York, an additional member to represent the city of New York

The colony is to have a medical superintendent, steward, matron and such teachers and other assistants as are necessary

The main object of the colony is to provide for the indigent epileptics of the State, but private patients will also be admitted to an extent to be determined by the Board of Managers Epileptics of all ages are to be received and cared for, minors are detained by authority delegated by the parents or guardians adults are free to go or remain, as they choose, there being no deprivation of liberty of any kind by methods of legal commitment, such as are necessary in asylums for the insane The charge for maintenance of indigent patients is to be borne by the State and a limit of $250 per annum per capita is established by the law But it is expected that the colony will eventually become, to a very great extent self-supporting

Patients that become insane are to be sent to asylums in the districts from which they come, in accordance with the lunacy statutes

A special pathologist to reside in the community and devote his sole attention to the discovery of the causes and cure of epilepsy, is one of the features ultimately contemplated in connection with this great institution

This bill was, unfortunately, vetoed by Gov Flower for reasons best known to himself, and the humane measures for the relief of the thousand epileptics already upon public charge in New York State is therefore postponed for a year or two

The care of the epileptic population is then summarized as follows

All are to be treated in accordance with the usual regulations as to diet, hydrotherapy and medicinal agencies, with the hope that in this way between 1 and 6 per cent of them may be cured and the disorder in a larger per cent ameliorated

Out-of-door employment in agriculture and kindred pursuits is to be provided in abundance All manner of trades and occupations are to be carried on in an epileptic community, organized on the village plan Facilities for education are to be afforded to almost every extent

Amusement and entertainment and the enjoyment of social intercourse are to be privileges from which no epileptic will hereafter be debarred

In this way the happiness of a large number of these miserable creatures will be materially increased, in spite of the distressing disease which they are called upon to suffer, usually for the whole of their lives, and though medical agents applied to their malady may prove inefficient their fate can never be as wretched and hopeless as it has been throughout the world heretofore

Although it is not given to every epileptic to describe his own sufferings as Dostojewsky does in his novel "The Idiot," or to delight the world with music as did the epileptic, Handel, or with comedy as did Moliere, or with poetry as did Petrarch, or with military exploits as did Cæsar and Napoleon, or with religion as did Mahomet and St Paul, still it is a consolation to those afflicted with this malady to show that epilepsy and genius may coexist, and that the possession of the disease does not necessarily lead to mental and moral degeneration The patient may not reach the highest position among mankind, but under the new dispensation he will not be withheld from any attainment in education, nor prevented from exercising all of his capabilities for his own support and for his own welfare and happiness

ABSTRACT OF NOTES ON THE TREATMENT OF EXOPHTHALMIC GOITRE

Read before the Section of Neurology and Medical Jurisprudence at the Forty fourth Annual Meeting of the American Medical Association

BY J MADISON TAYLOR, M D

NEUROLOGIST TO THE HARVARD HOSPITAL ASST PHYSICIAN TO INFIRMARY FOR NERVOUS DISEASES PROFESSOR OF DISEASES OF CHILDREN PHILADELPHIA POLYCLINIC, ETC

Dr Taylor takes up the subject of exophthalmic goitre as understood at the present time, reviews its relationship to other vascular disturbances, associated with enlargement of the thyroid, as myxœdema, cretinism and acromegalia He does not see that at present the thyroid physiology warrants any large measure of hope that we shall treat this malady through thyroid juices, as in the case of the other disorders mentioned, and yet promises to explore this field later He confines himself chiefly to the analysis of a number of cases long under his care, some of them for many years, and most of whom are well, summarizing the means through which these were improved The treatment of maladies which demand but little constant supervision, and yet require prolonged watchfulness, is more or less difficult and unsatisfactory because such cases wander away, will not persist in treatment, and from their nature of unhopefulness have a tendency to fall into the hands of other medical men and have their treatment changed, also the exigencies of labor, fatigue, changed surroundings, etc, make it difficult to pursue any consistent plan, even with those inclined to be faithful He takes the ground that this disorder is capable of much more hopeful treatment than is generally thought, that most cases are enormously improved, if rightly handled, that many get well

The question of treatment is chiefly considered from the standpoint of his own experience This consists in

1 Regulated rest, with carefully graduated activities as time and circumstances warrant, systematic measures directed to the upbuilding of the general health, careful attention to nutrition, recognizing the trophic elements in the disorder

2 Careful attention to vascular conditions, which are most noticeably at fault and which demand the most constant treatment This consists of varying measures, regulating vaso-motor activities, as well as loss of nervous force through the easily disturbed nervous balance This is done through attention to the skin from the surface by means of carefully regulated measures from without, and next the re-

view of certain remedies which seem to exert a control over the constant tendency to vaso-motor or neuroses, both superficial and deep

3 To search out constitutional defects and remedy these, eliminate accidental poisons, either diathetic or temporary, eliminate toxines, as of internal sewage poisoning, which has a very direct bearing

4 The regulation of the nervous or emotional balance by careful attention to the habits and environment of the individual, carefully regulating, so far as is possible, the habitual emotional strains and the possible ones, making much of moral teachings to those whose will power and mental equilibrium are gravely at fault constitutionally, and as inevitable entanglements due to months or years of suffering and susceptibilities

5 A careful consideration of such measures as are regarded as specific, as electricity, of which much has been made by many writers, but whose value consists chiefly in the system and encouragement which is thereby exerted over the disordered emotional states

Finally, a summary of the cases under observation when the original paper was written in 1888, the report of a number of others seen since then, and a careful review of the symptomatology and recent means of treatment

---

A METHOD OF LOCALIZING POINTS IN THE HEMISPHERICAL GANGLIA

Read in the Section of Neurology and Medical Jurisprudence, at the Forty fourth Annual Meeting of the American Medical Association

BY WILLIAM FULLER, M D

GRAND RAPIDS MICH

I will present to the Section the result of my work in the line of the subject given which I think is of value, since it enables one easily and expeditiously to locate any part of the surface or internal structure definitely, and with a precision that can be arrived at in no other way I have hardened a brain with great care so as to maintain the natural shape as nearly as possible The lateral halves were separated in the median line and each embedded in tallow, taking care to place each half in the same positions in the boxes surrounding them Each half was carefully sliced by a gauge so that the slices were three sixteenths of an inch thick and perpendicular to a line in the long axis of the brain, which was seven inches in length, making thus thirty-seven slices of each ganglion The right ganglion was cut three thirty-seconds of an inch behind the left and photographs were taken of the divided surfaces of each slice By this means I have obtained photographs of seventy four vertical transverse cuts of the brain The left side of the picture seen in the album is therefore three thirty-seconds of an inch behind the right, throughout the series which I now present for your inspection

I have here a model which is roughly made to illustrate the principle of localization We will suppose that the slices here represented are equal in thickness, the external markings are faithfully delineated and with photographs of the sections pasted upon the sections, the entire anatomy of any point beneath any portion of the skull can be taken in at a glance To find as near as it is possible any point within the brain, it is only necessary to draw a line from the exterior angular process to the occiput, divide the line into an equal number of spaces with the model, and the slice of the same number on the model will disclose the anatomy of any point on the skull, or direct the position of any point required to be found as well as the relative positions of the internal structures Prints of these photographs properly numbered would, in my opinion, be useful for the delineation of gross lesions of the brain for publication, which would be a means of familiarizing the profession with the anatomy of the brain, and would moreover assist each of us to understand the other Suppose, for instance, that a lesion is delineated upon a certain section definitely localized by a model and extending through a certain number of sections, it appears to me that we could perhaps some time arrive at a just conception of the function of the various parts of the brain There is little interest at present taken in the postmortem appearance of the brain, on account of general ignorance of its anatomy and from an unsatisfactory knowledge of its functions

I have been interested heretofore chiefly in surgery, I have given some attention to the surgery of the brain, and I will take this occasion to rectify a mistake into which the profession has fallen It is accredited to a French surgeon that he was the first to introduce surgery into the treatment of mental defects The fact is, however, that in 1877 I made the first craniectomy for the relief of idiocy, which was published in the *Canada Medical and Surgical Journal*, of January, 1878 I not only operated upon two cases at that time, but also published a paper upon the causes of idiocy and other conditions of feeble mindedness The publication of these cases was widespread, and the operation was ridiculed in both America and Europe in medical journals and by the press If there is any credit in the way of priority in the procedure, it belongs to me, since it was I who was the object of the ridicule I think, however, now as I did then, that the operation is of little benefit to the idiots or to the surgeons either, but that it is suggestive of a fact which may be of the greatest benefit to mankind, by giving material for reflection to the theologist and the educator, and for the instillation of charity into us all When all men are practically convinced that mentality depends upon physical conditions for its manifestation, mental defects will be regarded as diseases of the body now are, proper remedies will be sought, pity will take the place of anger, science will furnish texts the church with all other human things will perish, religion will reign in its stead, and a school system will be established upon reason, our children will then grow up into perfect adults instead of being precipitated into early graves and crowding asylums and prisons as at present ' The peculiar symptoms manifested by disease and postmortem appearances are interesting material with which to educate astute physicians, but it is a sort of cannibalism after all that one should be sacrificed that another may be great It is for us to initiate a revolution in mental sanitation, since those to whom this duty is intrusted are too bigoted to see when facts are plainly presented for their consideration

THE CHAIRMAN—*This* is a matter of very great *interest* I especially commend the practical suggestion *about* making brain examinations The photographs will bear careful examination The *work* shows a great deal of industry and skill on the part of Dr Fuller

Dr H H Donaldson, Chicago University—It was last winter that I first had the opportunity of seeing Dr Fuller's preparations, and I have not seen the one which is here upon the table before Those which I have seen are exquisite casts of preparations from the dissected hemisphere, showing the course of the white fibers and a number of points than which I have never seen any better preparation This is an idea which, I think, has been floating in the minds of a number of people for some time, but it has only been realized as regards the brain by Dr Fuller, so far as I am aware There is a French model which shows an enlargement of the medulla, which has been arranged in somewhat the same way, but the model has been magnified ten diameters and the magnification is in itself a disturbing factor, and there is no doubt that the student and others interested in the state of the central nervous system would be able to derive great advantage from the study of a model of this kind I may add that in the Anthropological Building at the Exposition, Dr Fuller has consented to exhibit a full series of his preparation

The Chairman—I would like to say that these sections have interested me very much, as I have occasion to do some postmortem work in this line from time to time, and it seems to me an admirable way of localizing, and it points out the way of describing the situation even of small lesions and of the beginning and ending of larger lesions, it would be well, I think, if Dr Fuller would publish a careful statement with the accurate reference of certain of these sections to the position on the surface of the brain where they are met Often it is important in describing a lesion of a ganglion and particularly in the interior of the brain to have not only the transverse positions, but also the exact position and extent of the lesions This system should be carried out in three directions, at least, to be perfectly accurate and advantageous, that is, horizontal sections and sections longitudinally and transverse sections These would answer for many purposes Practically the number of sections is too great for book purposes or publication or to suggest as a method of record, and I should think in the sections which include only the ganglia and certain standard sections it would be important to indicate those more thoroughly and definitely It is certainly a valuable method, and with additions, I believe, in the directions which I indicated of taking the sections in different directions and getting the appearances, it would be of great service

Dr Hughes—As far as my knowledge extends, I think that this is the nearest approach to a practical method of teaching students the regional anatomy of the brain extant I never saw any sections or anything in Europe that approximated this in completeness These sections and the models that the doctor makes, which are models of clearness and accuracy, I have found to be exceedingly valuable in the illustration of the anatomy of the brain in connection with my teaching in a large medical college To those of you who have not seen the other models that the doctor makes—some of which were presented last year—I would say that these, in connection with those, enable one to make the essential regional anatomy of the brain so plain to the student that there is no excuse for his failing to have a fair working knowledge of what is necessary in the treatment of brain diseases You will find that with the use of these models the relation of the external and internal capsule and the position of the ventricle, etc, become as familiar as a, b, c, and as plain as the regional anatomy of the liver and spleen

The Chairman—It seems to me that it would be well if the doctor would make the second part of his contribution as a separate note It seems to me to be a note of priority as to the suggestion of the operation of trephining for idiocy, and the secretary will note it in this manner Certainly he should have the credit for this, as it precedes the operations and suggestions of all other surgeons on this subject

Dr Fuller—There is one thing I would like to say, when I started in on this anatomy, I started in to interest myself, but after I went to the American Medical Association last year, there was a gentleman wanted me to see if I could repeat the experiments I went home, repeated them, and I thought I would like the benefit out of these things if I could financially, as it would cost me a great deal of trouble and expense, and I, of course, could not manufacture them myself, but tried to get somebody to do it for me The first thing I was asked was if I could furnish protection I could enlist capital if I could get protection I got a lawyer to send down a couple of sets to Washington, but of course they could not see that it was a work of art and consequently, though I could take out a patent on each piece, which was so expensive a process that I could not stand it, I could otherwise obtain no protection I consider this the same as a book or a work of art, but they could not see it in that light, consequently I have no protection on the preparations I thought if these things could be included as works of art, if we could bring some influence upon them to look at them in that light, I could get these things out in such a manner that everybody could avail themselves of them, but as it is now I can not get any further You will have to do something to help me out of this difficulty

Dr Hughes—What do they call it?

Dr Fuller—They could not call it anything It was innominate It will have to be specially mentioned and brought to their notice by some special request to influence their understanding, and I know I can take out a patent if I desire, but that would be a great deal of expense I find that the intermediary wants about all there is in it, he wants me to work for nothing and himself to charge the profession a big price, so that I am afraid that I will have to get you to assist me in some way to have this so that we can copyright it, or else I will have to keep along in the old way and try to make a living at the practice of medicine I think there is some money in this if it could be fixed in a way so that I could do something with it, and it will be of some benefit to the profession If you could make some recommendation to assist me in getting those things copyrighted instead of patented, I would try to do all I could to present the profession with something so that they could teach students these things easily

The Chairman—I do not see how we could take any steps in this matter

Dr Fuller—Books are copyrighted, I do not see why I could not copyright this

The Chairman—I do not see any reason why it should not be done, but I do not know whether that matter would be helped in any way by any special action of the Association Perhaps it is better at any rate to refer the matter to a committee than to attempt to decide it here Certainly the Association will gladly endorse the creditable character of the work by a resolution if necessary

Dr Fuller—The only way to get at it is to influence the authorities at Washington to give a copyright, the same as they would on a book

The Chairman—I would suggest that this matter should come up under the head of business, then it could be referred to a committee if it is deemed wise on the part of the Association

Dr H H Donaldson—One point connected with the latter matter In case Dr Fuller sees his way clear to carry this matter any further, I think it would be extremely valuable if the two types of brain could be taken, giving model forms of each type, that would be only possible, of course, in case Dr Fuller could realize his ideal in regard to the carrying on of his work

SANITARY MOTES AND BEAMS

Opening Address of the Section on Hygiene, Climatology and Demography, Pan American Medical Congress, by the President

ALBERT L GIHON, A M , M D

MEDICAL DIRECTOR U S NAVY

'And why beholdest thou the mote that is in thy brother's eye, but considerest not the beam that is in thine own eye?"—(St Luke, vi , 41-42)

These words of the Teacher of humanity which "the Beloved Physician" of the first century has recorded, are an appropriate text for the opening address in the important Section with whose conduct I have been charged in this Congress

Time was—and that no long time—when Hygeia, the neglected Cinderella of the medical family, slunk unnoticed among menials Now that she graces the salon her proud sisters caress her and suitors court her favor As an old admirer of this fair mistress whose colors I have worn through youth and manhood, I may be pardoned the personal exultation that I have lived to see her suzeraine

The ascendency of hygiene has greatened and glorified medicine without dimming the luster of any other branch, but though her cult is established, her mission is not ended with the recognition of her supremacy and the faithful following of her own ilk To day she turns to the people and their rulers outside the medical fold and demands the place in their councils that is hers of right A makeshift share in the administration of the sanitary interests of the country has been grudgingly allowed, but the inexorable demands of modern enlightenment can not be satisfied until the conservator of the public health shall sit a peer among the rulers The minister of war may build mighty engines for destruction and defense and muster vast armies and navies, which disease can disperse with a weapon so tiny that the eye can not discern and no mere military expedient antagonize The minister of finance may fill his treasure-houses with gold and silver by the ton, which can buy human souls—honor, virtue, independence—everything but the boon of health, God's free gift to man, through which alone he can be like His own glorious image Commerce, agriculture, manufacture, fishery, mining and all the industrial occupations of the human race, which are now the objects of the intelligent supervision of cabinet ministers, who are grand-masters of political economy and social science, can not thrive without vigor of human blood and brains and brawn, which are the machinery of these occupations, yet until this decade it has not been thought that the intelligent supervision of a grand-master of the divine science of medicine was necessary to preserve this vigorous health of the community, without which even these other ministers can themselves only imperfectly perform their own offices of administration

When I entered the service of the Government of the United States as an officer of the medical department of the navy, nearly forty years ago, with a minimum of experience and a maximum of enthusiasm and an exalted opinion of the dignity and responsibility of my charge, which a lifetime has only intensified, I was astounded at the total ignorance of sanitary provision then prevailing in the naval service Medical officers were curtly reminded that their opinions and advice would be asked when desired, their protests at acts that filled the hospitals and mortuary lists were contemptuously unheeded, they were reproved for officiousness and punished as insubordinate, disabled sailors and marines were discharged and their places and those of the dead were filled without regret or remorse, but with the shameless boast that "if men die we can ship others ," like the Netherland commodore, some of whose crew had been killed by the careless firing of a shotted saluting gun, who accepted the apology for the accident with the nonchalant remark "Dere are plenty more Dutchmens in Holland "

The battle-ships and cruisers of modern navies are not more unlike the brigs and sloops-of-war of forty years ago, than are the cleanly, well fed, comfortably clad and cared for enlisted men, who go on shore daily, subscribe for newspapers and write letters, a different race from the begrimed and degraded "shell-backs," who were ordered to their work with curses and punished with brutality for offenses which neglect and ill-treatment had incited The naval and military establishments have considered the beam in their own eyes, but civil authorities are still purblind to the necessity for organized intelligent sanitary supervision and direction, and grope for succor only under the flash-light of a pestilential visitation

The following from a recent editorial in an influential journal is pertinent

> "Whether cholera has or has not made its appearance at Chester, which is practically one of the suburbs of Philadelphia, it is certain that the conditions reported to exist there are in the highest degree favorable for the introduction and spread of that disease All accounts represent the neighborhood in which the alleged cases occurred as filthy beyond description and occupied by a class of persons who pay no attention whatever to the laws of health or personal cleanliness Of course, the country now has the pleasant assurance that the place is to be thoroughly cleaned and effectively quarantined, but why were not the steps necessary for the protection of the public health taken before the resulting disease, whether cholera or not, had gained such a footing that already five persons had died from it? The time to lock the stable door is before the horses housed therein are stolen, and the way to treat contagious diseases is to prevent their appearance and not wait for them to gain a foothold and then try to stamp them out"

The Secretary-General has announced that the proceedings of this Section and its congener, the Section on Marine Hygiene and Quarantine, will constitute a special feature of this Congress It is, therefore, incumbent upon us before adjourning to declare very positively the opinion of the members of this Section, experienced practical sanitarians from every country of the western hemisphere, that the interests of the public health must be intrusted to a department of the Government especially charged with their administration, with equal, independent, executive authority, as given to other National departments Temporary legislation under the spur of emergencies does not befit this age As the enlightened physician seeks to prevent his charges becoming ill, so should the guardian of the public health be able to forestall those emergencies, whose pecuniary cost in money expended and wasted, in trade paralyzed and diverted, in labor and its wages lost by the sick and terrified and dead, in a single epidemic, exceeds that of maintaining an efficient sanitary service *for the whole country* for a whole year

The fault of the medical profession has always been its lack of bold assertion of its rights, but it can no longer hesitate to declare to trade and commerce and agriculture and manufacture that the health and vigor which are essential to prosperity can not be secured by their own unskilled uninformed efforts They must learn, as the military services have learned, that powerful armies and navies are the result of able and untrammeled medical departments It is as unwise to confide the care of the National health to a financier, however astute, as to expect a postmaster-general to understandingly control a bureau of agriculture, a fishery commissioner to best administer the affairs of the public schools, and an attorney-general to direct the mining industries The health of a nation is a National consideration, involving international cooperation There should be no priority nor clash of sectional interests State lines are not respected by epidemic intruders No State barrier can be so defensive and impenetrable that the toxiferous germ can not pass through The precise form of administration may be left to legislation, the indispensable requisites being that it shall be National, that it shall have parity of voice and influence in the National councils, that it shall have independent executive authority under the limitations common to other departments, and that it shall be intrusted to educated and experienced medical men, who alone are competent to assume its responsibilities [1]

I have not wandered from my text in thus pleading for a National public health establishment Spasmodic tentative provisions in emergencies are nothing but attempts to discover *motes* from abroad, when the *beams* at home should first receive consideration To parallel further and in another sense, the scientific tendency of the day is literally towards *mote-hunting* through microscopes, instead of using our human eyes upon visible abominations The sanitarian, official or amateur, needs but look about him to be appalled at the spectacle of indifference of rich and poor, high and low, to dangers far greater than any from cholera microbes, which confront them every hour, and it may be worth our while to indicate some of these beams in our own eyes, which we complacently refuse to see, while we magnify the motes on our horizon

The preventable disease, which kills more of the human race than cholera and yellow fever together, and in its ordinary slow process of killing lessens the productive power of a community, directly by the enfeeblement of its victims and indirectly by its demands upon members of households and eleemosynary institutions for the care of these chronic invalids—*tuberculosis*—is tolerated with as little concern as the Mongolian exhibits for smallpox, or the Creole for yellow fever or malaria The consumptive whose traits no professional acumen is required to recognize, frequents our crowded thoroughfares, sits beside us in unventilated street cars, and at the hotel table, occupies Pullman sleeping-berths and shares the steamship stateroom, wholly unrestrained and innocently ignorant that he or she may be sowing the seeds of disease among delicate women and children Any one may verify this who uses his eyes for the purpose along the railway and coastwise steamer routes to our invalid resorts Within a twelvemonth, on my way to Mexico by rail, I was fellow passenger with two invalids in the advanced stage of phthisis, en route for San Antonio one of whom occupied the opposite berth, and the other one diagonally across the car, so that I could see and hear them coughing and expectorating, with only such attention as well-intending but unskilled relatives could render They had no vessels for receiving their sputa, which was discharged in their pocket handkerchiefs, to be scattered over pillows, coverlets and blankets They left the car in the morning, and I saw those same berths, it is true with change of linen sheets and pillow-cases, but with no change of blankets, mattresses or pillows, occupied that very night by other travelers, who were thus subjected to contact with a pathogenic microbe far more tenacious of life and power of evil-doing than the dreaded cholera spirillum One has only to sit in a crowded street car on a winter day and watch the clouds of respiratory steam circling from the mouths and nostrils of the unclean and diseased into the mouths and nostrils of the clean and healthy, as the expiratory effort of the one corresponds with the inspiratory act of the other The road is short but straight and sure from vomica and mucous patch to the receptive nidus in another's body Who that has ever had forced upon him an aerial feast of cabbage, onions, garlic, alcohol, tobacco and the gastric effluvia of an old debauché can doubt that aqueous vapor can transport microscopic germs by the same route? Not long ago I traveled by sea from New York to Charleston, and for two nights was cabined with some twenty consumptives going to Florida The air was chill, and they huddled around the stoves and fearfully and fearlessly closed doors and windows, until the atmosphere became stifling with their emanations and the dried sputa, which they ejected on every side It was comparatively easy to escape during the day by staying on deck, and I slept with my stateroom windows wide open, but the curtains, carpets, pillows and mattresses had been saturated by I know not how many expectorating predecessors I have visited fifty smallpox patients a day, have gone through yellow fever wards and stood by cholera bedsides with far less apprehension than I experienced on that trip, yet it was one taken by many thousands of people, who would have been terrified to know that there had been a case of cholera within a mile to leeward of their homes Recall in your several experiences the instances of members of a family, who have occupied the same chamber and bed with a gentle and beloved aunt or sister, and those of tuberculous husbands or wives, who have become ill like them with pulmonary phthisis attributed to everything but the manifest cause

In former years, I preached a crusade against another virulent communicable disease, in the interest especially of innocent and helpless women and children, and for a time I was gratified to find that husbands and fathers began to realize from the numerous indisputable instances I was able to report, that *syphilis* might be, as it had been, contracted from combs and brushes and rough edged drinking vessels in hotels, sleeping cars and boarding houses, from pens, pencils and paint brushes, that had been held between diseased lips, from dirty, old banknotes, from street vendors' toys, from a lover's kiss, a stranger's caress, or a nurse's ministrations Supported by an array of cases of infected children, young girls and elderly men and women, the committee of the American Public Health Association, of which I was chairman, advocated the enactment of a law, placing venereal disease in the category of other communicable affections and punishing its transmission as a misdemeanor, but there were too many of the self-righteous blind to these beams in their eyes, who thought it wiser to seek to exterminate by ignoring its existence and never uttering the name of a disease that has done more harm to mankind than all the diphtheria, typhoid, smallpox, measles and scarlet fever, which are so carefully isolated and their statistics so regularly collected and promulgated—a disease that travels with the missionary to Asia, Africa and the Pacific and decimates bodies faster than he can whiten souls

---

[1] These propositions were unanimously adopted in the form of a resolution in these terms by the conjoined Sections on Hygiene Climatology and Demography and Marine Hygiene and Quarantine and reported to the general session of the Congress by which it was referred to the International Executive Committee which returned it with its endorsement and direction that it be transmitted as the view of the Congress to the executives of all the countries represented therein

I do not expect that all who have eyes will see as I do, or having ears hearken to what I say The idle and perverse generation of the first century will have its following in the twentieth, and men and women will continue to do the insanitary things they ought not to do, and leave undone the sanitary precautions they ought to take despite our warning, our imploring, our advice or our denunciation However benevolent and beneficent the hygienist's aim, this unappreciated, unrequited and often unprofitable labor is enough to deter him from what has been derisively described as only an effort to procure the survival of the unfit—and thus thwart Nature's own attempt to rid the world of them He encounters another obstacle to success as aggravating as the disbelief in the necessity for his work The authorities listen to his warnings and then employ their own perfunctory and superficial methods of protection Told that absolute cleanliness is the fundamental fact of sanitation, street-cleaners are set at work brushing the surface dirt into little heaps, which passing vehicles again distribute or the winds carry into the opened windows of adjacent residences The refuse of the household is deposited in vessels on the sidewalks of crowded thoroughfares to be emptied after a time into collecting carts, from which clouds of dust envelop passers and circulate back into the houses—*living* dust, for Manfredi found an average of 761,521,000 microbes to the gram of the street dirt of Naples, from which he cultivated pus, malignant œdema, tetanus, tubercle and septicemia Swarms of flies feed on the decomposing contents of exposed garden pans and buckets and carry their tiny germ laden booty into the butcher shop of the poor and the kitchen of the millionaire Who can dispute that if the hair of the Newfoundland dog could transport yellow fever to a distant Mississippi town, and a newspaper printed in an Ohio village where smallpox was raging, could fatally infect a United States Consul in a foreign port where the disease did not exist, that a cloud of dirt, a swarm of flies, or a single fly, as Sawtschenko, Simonds and Steinberg demonstrate, can disseminate cholera and become a focus of infection, which ordinary precaution to cover and destroy the discharges and excreta of those already sick would have made impossible? Cities are reported clean whose sanitary inspectors have merely walked through crowded tenements, a hundred or more a day, and been satisfied with external evidences of brush and broom, leaving carpets and rugs unlifted, pieces of heavy furniture, with the fluff of years behind and beneath, unmoved, and closets, cupboards, pantries, storerooms, attics and cellars undisturbed The cellars of our great cities, and I speak with personal knowledge of many in New York, Brooklyn and Philadelphia, are greater abomination than even filthy living apartments

The *New York Herald* of the 8th August, narrating the death of two children by falling from a window on the fourth floor of a tenement house at 204 West 61st Street, said "To get at the bodies of her children the frantic mother had to go through the cellar of the house There she waded through indescribable filth, almost knee deep to where her children lay, when the foul odors overcame her and she fainted" It added "The sanitary superintendent issued an order that the cellar must be cleaned out within twenty-four hours" Do you believe that it was the only one of its kind that needed cleaning? No city can be accounted clean until its ordinances require every cellar door to be widely opened to the sun and air—that royal pair of germicides—every cellar to be emptied of its refuse, every cellar wall and ceiling to be scraped and whitewashed, every cellar floor to be taken up if rotted and sprinkled with lime if uncovered, a tedious and expensive process, but effective sanitation, costly as it must needs be, is cheap beside the outlay of a single epidemic There are underground foulnesses in all our great cities, of which they should be rid at any cost, as where rag-pickers and bone gatherers collect their filthy stores, and Italian street-corner fruit sellers keep their decomposing bananas, grapes and oranges, till rubbed off by dirty pocket handkerchiefs they are exposed for sale, glistening after their repulsive polish with impure saliva If some mote hunter, loth to find so huge a beam, chooses to find solace in disbelief, I might be able to shock him by declaring that I have seen the figs he munches unconcernedly, flattened in their pretty boxes in a country where syphilis reigns, by questionable thumbs moistened by equally suspicious saliva Shall I, while revealing insanitary horrors, dare lift the sweeping train of the fair promenader, fashioned after that of women in other countries who never walk upon the streets, and show the nasty mess of spittle, excreta, mud and dust she gathers from the sidewalks upon her white skirts and silk stockings? She will not believe me, but the bacteriologist, who scoops the mud from between the cobble stones of the streets to find it swarming with microscopic life, can gather as rich a harvest of microbes from these same dainty undergarments

Nor are these the only beams we overlook in our search for motes Dr Graham, bacteriologist of Starling Medical College, in response to an official inquiry by a member of Congress, reported that he was able to obtain thirteen colonies of two kinds of bacteria from one dirty, worn banknote, and the *Medical Record* of 21st of January of this year, states that a British bacteriologist discovered 19,000 microbes, including those of tuberculosis, diphtheria and scarlatina vegetating upon a single note

Other harborers of morbific germs are the textile fabrics employed in the furnishing of street cars and stages, which the chairman of the Sanitary Committee of the New York Board of Health reports as "a menace to public health by reason of their continual exposure to uncleanness and infection from the clothing of diseased and filthy passengers," which, like their grimy bodies, may be foul with the sputa of diphtheria, tuberculosis or syphilis, the desquamations of scarlatina, measles or erysipelas, the emanations of typhus or the alvine discharges of cholera or dysentery A commendable league of zealous ladies, who are seeking to prevent the abominable practice of expectorating in public vehicles, induced a few car companies to display placards, to the effect that "gentlemen are requested not to spit on the floors," but these appeals intended for beasts, who were never gentlemen, were hung in inconspicuous places or covered by other notices, and the spitters continued to discharge their syphilitic and tubercular sputa on the floor mats to be taken on ladies' petticoats and carried to their homes The spitter and the other beast, who voids his nasal secretions where it suits him, are largely responsible for the spread of influenza, for, according to Pfeiffer, the discoverer of its bacillus, "its contagion is found in the moist secretions of acute cases in the discharges from the nasal and bronchial mucous membranes"

Further detail would be out of place in an introductory address to this Section Let it suffice to point to the fragile spirillum of cholera, which we are exorcising by "bell, book and candle" as illustrating the dreadful *motes* of my text, and to the sturdy robust bacillus of tubercle as the *beam* we will not consider "Cholera," says Ernest Hart, "can only be drunk and eaten It can not be caught and breathed," but the tubercular mischief maker, who finds the ever open door of the respiratory passages his readiest approach, may also enter at any or all the orifices of the body Among one thousand autopsies, Osler found 275 with tuberculosis, among 8,873 patients in the surgical clinic at Wurzburg, one seventh (1,227) were tuberculous, the necroscopic statistics of Harris and others "show that one-third, perhaps over one-half, of the people who live to middle age, have some form of tubercular infection, and Dr Williams of Johns Hopkins' Hospital estimates that tuberculosis of the female generative organs is four times more frequent than generally supposed" (*Medical Record*, March 18) Can any more obvious method of direct infection in these cases be imagined than the trailing skirts of women gathering tubercular sputa from the pavements?

The sanitary inspector is destined to become the most important agent of future civic administration The perfunctory burning of a pan of sulphur in a diphtheritic chamber, the sprinkling here and there of a solution of corrosive sublimate, or the substitution of the sweeter scent of thymol, pinol or some newer "ol" for the foul odor of the privy will not then be the tolerated limit of this interference All that science teaches and all that intelligence can devise will be exacted of him A sanitary inspection will be a deliberate, painstaking, critical examination of nooks and corners and their disinfection, the flooding of the lairs of microscopic motes and the deluging of unsightly beams with those unstoppled, unpatented, inexhaustible germicides, air and sunshine

Coincident with the approaching Eleventh International Medical Congress at Rome and its fitting complement, there is to be an Exposition of Medicine and Hygiene, and significant of the share accorded sanitary science in a Medical Congress representing the highest modern professional attainment, it will be noticed that of the *ten* classes which in their ensemble make up the Exposition, *five* are exclusively hygienic, to-wit

4 Plans, models and *materiel* bearing on school management and sanitary civic organization (*riordinamento urbano*)

6 Plans models and *materiel* for hygienic constructions

7 Apparatus and furniture for hygienic uses in the interior of common dwelling houses and public offices on every scale

8 *Materiel* appliances and accommodations for the practice of personal hygiene, and

9 Plans, models and appliances for the hygiene of the working classes

Three are partly hygienic, to-wit

1 Apparatus, *materiel* and plans of buildings for scientific and technical investigation in therapeutics, biology and hygiene

3 Articles and appurtenances requisite in salvage service and in *assistance publique*, and

10 Books, atlases, photographs and such like, recently published and having reference to the medical, biologic and hygienic sciences

Two only of the ten are exclusively medical and surgical, to-wit

2 Apparatus, instruments and *matériel thérapeutique* in the various departments of medicine, and

5 Plans, apparatus and furniture for the purposes of the divisional surgeon in cities Additional to these, special classes are devoted to hydrology and balneo-therapy, and to the Italian Red Cross Society, both of which are practical outcomes of sanitary endeavor

I do not forget that climatology and demography, as well as hygiene, are within the purview of this Section, but what are climatology and climato-therapy but applied hygiene, and what demography but the demonstration of the results among masses of people of sanitary or unsanitary conditions? The climatologist is of necessity a hygiologist The materia medica and pharmacopœia are not his text-books Physical geography, meteorology, hydrology, balneology are his scriptures and gospels The vivifying light, invigorating air and healing springs and waters his armamenta, his anodynes and hypnotics, his roborants and entrophics, his alterants and excernents The high professional standing of the American Climatological Association, one of the constituent bodies of the Congress of American Physicians and Surgeons, and the distinguished climatologists who are with us to-day and who are conspicuous in every International Congress of Hygiene, are evidences of the place in medicine of climato-therapy, the practical end of medical climatology, that broad specialty which robs so many graves of untimely victims and makes so many heretofore without hope able, if not to take up their beds, at least to get out of them, and walk The field of the climatologist is broad as the habitable surface of the globe—in the high altitudes of Colorado and the Alps, in the odorous pine forests of Norway and the Carolinas, on the sea shore or upon the wide waste of waters and their islet oases swept by ocean breezes

Our American vital statistics are not yet piled high enough to form the foundation for a substantial superstructure of demography The great caldron in which we are mixing Celts and Saxons, Semites and Aryans, with a seasoning of syphilis, tuberculosis and insanity, is simmering, with what ultimate homogeneity can only be conjectured When immigration was a tiny stream, however muddy and noisome, poured into a rapid river of pure water, it was soon lost in the crystal fluid, but now that huge sewers are discharging their fetid pestilential torrents into a placid lake that has no outlet, the lake itself becomes turbid and unclean Already, in the *cul-de-sacs* which are nearest the open mouths of these foul sewers and receive their floating scum—the prisons, reformatories, almshouses, insane asylums and hospitals—this filthy, debased and diseased foreign element is ascendant, and our demographers have a simple task in representing its volume by numerical statistics Dr Frederick H Wines, the distinguished compiler of this portion of the census of the United States for 1890, demonstrates by the indisputable evidence of figures that while the foreign born constitute only 17 per centum of our total white population, in round numbers about one-sixth, yet they furnish over one-half of all the paupers in the almshouses of the country It is evident that the traits of the Saxon are disappearing from our National complexion, and if the proper solution of the negro question be, as suggested by certain prominent Afro-Americans, to bleach it out by admixture, we may expect the hue of our descendants to be decidedly tawny

The most zealous demographers of this decade are the French, who have been spurred in their statistical researches to discover the causes of the too evident depopulation of France of its native races But are we not again refusing to consider the beam in our own eyes in not giving heed to the operation of similar conditions in our own country? Dr Billings announces that our birth rate has fallen from thirty-six per thousand inhabitants in 1880 to thirty-one per thousand in 1890 The twenty to thirty children of our ancestors, the dozen or more of our great-grandmothers, have dwindled progressively to five or six, then to three or four, until to day one or two or none represent the fecundity of the educated classes The *Independent*, referring to New England Puritan life, says

> "Large families abounded According to Cotton Mather' one woman had twenty-two children, another twenty-three by one husband, and a third was mother to seven and twenty Sir William Phipps was one of twenty six children of the same mother Printer Green had thirty The Reverend John Sherman of Watertown had twenty-six children by two wives, the second spouse the mother of twenty The Reverend Samuel Willard, the first minister of Groton, had twenty children, being himself one of seventeen, as was Benjamin Franklin"

The paragraphist who can now record the case of the woman of 31 at Cold Spring who has become the mother of seventeen children in nine years, or that of the Georgia matron of 25 who rejoices in thirteen, has, in newspaper parlance, "a great find" The spectacle of impending maternity among our better classes is becoming more and more rare, and still more rare that of an infant nursing at its mother's breast Only in the squalid quarters and purlieus of our great cities where the English language is not spoken among imported lazzaroni and the overflow of Italian ghettos, does the process of human incubation go on as God and Nature intended The laws of creation are immutable, and one has but to look beneath the disfigurement of female dress to recognize the evidences of imperfect physical development—in stooping unsymmetrical shoulders, in meager limbs, in narrow pelves and flattened busts Dr Dr Otis exhibited at the recent meeting of the American Climatological Association in illustration of the diametric measurements of the thorax, the profiles of a number of female chests which were supposed to be those of little girls until he explained that they were the contours of nubile young women in Boston normal schools, like her whom Solomon bewails in the Song of Songs "We have a little sister and she hath no breasts what shall we do for our little sister in the time when she shall be spoken for?" My friend, Dr Robert T Morris of New York, has called attention to the fact that eighty per centum of all Aryan-American women have rudimentary clitorides and asks if evolution is trying to do away with this organ in the degenerative changes characteristic of highly civilized varieties of the *homo sapiens*, of which early falling hair, decaying teeth, weak mammary glands and badly balanced eye muscles are other examples Is the sexual instinct losing its potency as a maternal factor? Is marriage only a social office for the display of finery on the bride and bridesmaids and the entertainment of crowds of gaping strangers? Is the virgin wife best prepared for conception by months of preliminary sur-excitation and feverish anxiety, and is a fatiguing railroad journey the best prelude to an act which should lead to the inception of a human being, the incarnation of a human soul? Has the function of reproduction come to be regarded only as a bestial concomitant of matrimony, and lactation its vulgar indecent supplement, and is all this attributable to physical deterioration shown by the undeveloped or imprisoned *mentula muliebris* and atrophied mammæ, and how far is this the explanation of the diminished fecundity of the Aryan-American woman? These are problems as interesting to our demographers as the depopulation of France, the disappearance of South Sea Islanders, the migration of Semitic and Mongolian races, and the effects of mal-nutrition on the indigenes of Ireland and Russia

But, gentlemen, I shall no longer trench upon time that belongs to you I am highly gratified at your presence and thank you most cordially for your kind attention

NOTE —The remainder of the address was delivered in Spanish, of which the following is a translation

Gentlemen our Friends and Colleagues from Abroad —Permit me on the part of the members of this Section from the United States of America to tender you a most hearty welcome to our capital Your long travel to this city bespeaks your interest in the occasion It is no light boast that here for the first time in its history the medical profession of all America finds itself united in one great Congress It was about nine years ago that a number of Canadian sanitarians claimed the right as Americans to become members of the American Public Health Association and it was my privilege as president of that body to receive them as such. The subsequent transactions of that Association show how loyal they have been to its traditions, how zealously they have participated in its work and with what dignity they have filled its highest offices Two years later they carried the Association into their own territory at Toronto

In 1890 two distinguished representatives of the Supreme Council of Health of our sister republic of Mexico came to Charleston and as Americans, likewise knocked at the door of the American Public Health Association, returning the following year in such numbers and with such a hearty welcome from their government to meet in their own capital that the invitation was accepted and the most successful meeting of the Association, the twentieth in its history, was held in the ancient city of the Toltecs To day the roll of States represented in the Advisory Council shows Illinois Massachusetts and Tennessee Ontario, Quebec and Manitoba Guanajuato Querétaro and Zacatecas in one fraternal union

What sanitarians have done in that Association which bears the escutcheons of its three constituent countries, side by side this Congress aims to accomplish for the whole profession of medicine in the Western Hemisphere, uniting its members in one brotherhood, whatever their race or language and whether their homes be *on the frozen* shores of the Arctic or the hillsides of Tierra del Fuego among Greenland's icy mountains in the archipelago of the West Indies or amid the perennial gardens of Hawaii

Physicians and brothers from the United States of All America welcome to this your capital which in that sweetest language spoken by human tongues, *pongamos á nuestra disposicion*

Medico-legal Photography —One of the recent inventions in photographic science is exhibited *in the French building* at the World's Fair It consists of a reversible camera, with a special tripod enabling the operator to photograph a corpse and the surrounding area of ground in the proper perspective to an extent of about eight feet square The tripod is placed over the object and focusing is obtained by means of a mirror at the back of the camera with an angle of 45 degrees By this method the condition of the ground and contiguous objects in their most minute details are fixed upon the sensitized plate

CHOLERA, ITS NATURE AND ITS CURE

BY HENRY RAYMOND ROGERS, M D
DUNKIRK N Y

"We have no better means of combating the cholera to day than at any time since it became known to civilization, a thousand years ago," said a distinguished physician in a recent number of the *Review of Reviews* The medical profession therefore stands confronted with the appalling fact that hitherto all theories of this disease have been so misleading, and all forms of treatment have proved so worthless, that longer to trust them would be little less than criminal Better theories and practice are urgently demanded

The bacillus theory of Dr Robert Koch, which was so eagerly grasped at, is now found to be fallacious Dr Koch himself admits that comma shaped germs are found in the common diarrheas of summer everywhere, and he tells us "Water, from whatever source, very frequently, not to say invariably, contains comma-shaped organisms" He is not ignorant of the fact that these bacilli are found in the secretions of the mouth and throat of healthy persons and in the dejections of hardened fecal matters Dr Koch also knows full well that Drs Pettenkofer of Munich, and Emmerich of Berlin, two of the most distinguished members of the medical profession of to day, and experts in this disease, drank each a cubic centimeter of "*culture broth*" containing these pathogenic bacilli without experiencing a single characteristic symptom of cholera, though the draught in each case was followed by liquid stools swarming with these germs Hasterlik reports six cases of the same kind without any apparent results The utter worthlessness of Dr Koch's comma bacillus as diagnostic evidence of this disease is thus fully demonstrated

As the result of a personal experience in every epidemic of this disease in our country since 1851, together with an experience of its effects upon my own person, and a success in its treatment quite phenomenal, I am prepared to assert that cholera need be no longer the dread and scourge which hitherto it has been

It is strange that a new philosophy of this disease which must revolutionize its theories and its treatment is now found where it never before has been sought for, but where alone it is possible to find it, viz in the right interpretation of the symptoms which characterize the disease This philosophy not only reveals the essential nature of this disease, but points unerringly to a more successful treatment

The symptom of most vital importance, and the only one which is pathognomonic, is the watery exudations which find their way so profusely through stomach and intestines and skin In fact, all other symptoms which follow this one have their origin *in it*, since, in the entire absence of *this*, neither of the others can have an existence The most vital consequences, therefore, depend upon the right appreciation of this symptom, together with the promptness and efficiency with which its indications for treatment are carried out This watery element is constituted of the serous element of the blood, and comes from every part and portion of the system

The question now arises, by what process does this rapid separation of the finer element of the blood from the coarser take place? The nerves of the system, when in their normal condition, preside over and maintain the tonicity of every organ, vessel and tissue of the body They control the functions and processes of every part The rapid filtration of the watery element of the blood through the now loose and patulous walls of the blood vessels indicates a loss of tonicity on the part of the nerves which permeate those walls On account of such weakened condition of the walls of the blood vessels a general serous outflow pours from every vein and venule of the body, and the great life current is thus robbed to supply these so-called rice water discharges At the same time the weakened vessel-walls contract with diminished force upon their remaining contents, and consequently the brain and heart fail of an adequate supply, and the more fatal symptoms and death follow Such is the secret of the disease and its rapid and phenomenal fatality

The rapid abstraction of a single element of the blood becomes disastrous in the same manner as when the full blood itself is lost in the more common forms of hemorrhage It is, therefore, passing strange that this rice water phenomenon never has been recognized as a hemorrhage, with all that such a hemorrhage implies All symptoms and conditions incident to this disease, as also the changes observed upon the cadaver, are explainable upon the hypothesis of actual hemorrhage, and we are warranted in saying, *only* upon that hypothesis

Owing to the failure to discriminate between the actions of the red corpuscles of the blood and its white discs, its chief constituents, this hemorrhage hypothesis has not been applied in explanation of this disease The vital forces of the system depend largely upon the action of the red corpuscles, for through these chiefly are effected the oxygenation of the blood and the consequent revitalization of the system A small loss of this element may become quickly fatal On the other hand, the serum or white element which constitutes the bulk of the blood performs less vital functions, and its abstraction becomes neither so quickly nor so seriously manifest. In this disease enormous quantities are sometimes separated from the circulating current without fatal consequences

Treatment —Since the disease is essentially a neurosis, and its controlling symptom a hemorrhage, its treatment becomes at once clearly defined, and the pure empiricism of the past must give place to a scientific treatment with vastly improved results We must look upon the cholera hemorrhage as subject to the same general principles of treatment as other hemorrhages

As the cholera hemorrhage occurs over so large a portion of the body, is colorless, and therefore virtually a *concealed* hemorrhage with all that is alarming which that word implies, it calls for attentions at once prompt, efficient and watchful No painless diarrhea or painless vomiting is free from danger during a cholera epidemic, since the milder conditions of the disease often quickly change to those more grave and fatal

Both the principles and the practice of medical science teach that position, *position*, POSITION, is the prime safeguard in sudden and profuse hemorrhages occurring from any cause In the treatment of cholera hemorrhage, position with the body horizontal or with the head the lowest, is quite as indispensable as in that arising from any other cause

Position in the treatment of cholera is not simply a repose in bed with the head resting comfortably upon the pillow, and raised or lowered at the pleasure or caprice of the patient, but to be efficacious, as in its graver cases, it must be *compulsory*, and strictly maintained, *as for the very life*, until the danger period is passed The vital necessity of position in the treatment of cholera is shown by Murray, Cunningham and other distinguished authorities when they tell us that "once sitting upright in bed sometimes causes death in this disease" Not even in the act of evacuation of the bowels should the head be raised in the more serious cases But position in this disease is sometimes difficult to secure, as the patient, when weakened by exhaustive discharges and pain, becomes disturbed in intellect and is with difficulty controlled

If the best results are sought for, the horizontal position should be enforced in every case of even suspected cholera In cases of great danger the body should be inclined with the head the lowest This position should be maintained until the blood vessels contract upon their contents, which fact is shown by an improved condition of the pulse

In the present condition of medical science, opium and its preparations stand far above other remedies which may be employed in the treatment of this disease No remedy is known which surpasses this one in the power to change the perturbed condition of the nervous system and close up the diminutive avenues through which the watery element of the blood and the life ebb away together During an epidemic it is hazardous to rely upon remedies taken through the mouth, since in cholera the action of the mucous membrane often becomes changed, so that internal remedies either fail to act or are ejected Moments are sometimes precious, as a life may depend upon the certainty of retention of a remedy and the promptness and efficiency with which it may act The hypodermic method is here our best resource According to the reports of cases in Asia, Australia and elsewhere, the hypodermic use of morphia has shown almost uniformly favorable results, the one-eighth to the one-sixth of a grain of the latter very rarely need be exceeded or frequently repeated Opium and morphia *in large doses* are decidedly contra indicated *in any of its stages,* since, if these drugs are retained in the stomach, they may become cumulative and in the case of reaction they might become fatal

For the relief of the atrocious cramps, the administration of chloroform by inhalation, together with small doses of morphia hypodermically applied, offers the most speedy and effectual means at our command The stimulation of the brain by currents of blood sent to that organ by *position*, wonderfully facilitates the control of the cramps

For excessive thirst, ice may be given ad libitum, and if ice can not be obtained, the coldest water in small quantities and frequently repeated The suffering from thirst in this disease is inconceivable, and it is unjustifiable, unmitigated cruelty to withhold these necessaries from the sufferer Ice has been given freely in *every* case under my charge, and with the happiest effects

The circulation should be promoted by the application of heat and friction to the extremities Any further treatment may be conducted upon general principles

En résumé This disease, so destructive to human life, is thus found to be most simple in its character and positive in its indications for treatment As a problem in medical science, cholera resolves itself into a question of supply of blood to the brain and heart If this supply be kept up, a fatal termination to this disease is not probable Whatever course will best promote this end, therefore, must secure the most favorable results in its treatment

The inestimable value of *position* as the fundamental idea in the treatment of cholera was first exemplified upon my own person in 1854, and has been abundantly demonstrated in the epidemics which have since occurred

The simple theory herein advanced is found in entire harmony with the highest principles and practice of the advanced medical science of to day It offers results such as never yet have been realized, and places within the reach of all a ready method of treatment This treatment may be successfully employed even without the use of medicines

In fine, in the light of the study of this disease during forty years, both at home and abroad, such as few have had either the opportunity or the inclination to pursue, and in view of the phenomenally favorable results of treatment based upon this philosophy, I believe myself fully warranted in asserting that the rate of mortality of this scourge may be reduced to less than half of that at which it confessedly stands to-day

The foregoing theories have been presented by the writer before the American Medical Association, the New York State Medical Societies and the Chautauqua County (N Y) Medical Society, also through the columns of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, the *Chicago Medical and Surgical Journal*, and the *Quarterly Epitome of Practical Medicine and Surgery*

NECROLOGY

A Famous Irish Surgeon Dead—Dr T H Parke, who Accompanied Stanley through Africa—Dr Thomas Heazle Parke, a distinguished surgeon, and one of Stanley's most intimate and beloved companions in the latter's trip across Africa in 1887–88–89, is dead He was an Irishman, his birthplace being Ologher House, Drumona, County Tyrone Dr Parke was only thirty-six years old at the time of his death

He was commissioned as surgeon in the medical staff of the British Army in 1881, and from that time onward his life was spent in active service abroad The following year he was in the Egyptian campaign and received the Queen's medal and the Khedive's star He then went through the cholera epidemic in 1883, and afterwards was in the Nile campaign for the relief of Gordon Dr Parke was present at the battle of Abu-Klea, the action of Gubart and other engagements He went across the Bayudu Desert in medical charge of the naval brigade under Lord Charles Beresford and returned in medical charge of the Guards camel corps under Lord Falmouth

ACROSS AFRICA WITH STANLEY

Subsequently he crossed Africa with Stanley in 1887–88–89, and when he returned received many honors from societies, his government and the Khedive He was put in command of a company of the detachment under Major Bartellot, which sailed up the Congo on the steamer *Stanley* At one point of the journey, at Ipoto, Dr Parke was practically in the power of the natives He and his companions, separated from the main body, suffered severely from **want** of food.

CHOLERA, ITS NATURE AND ITS CURE

BY HENRY RAYMOND ROGERS, M.D.
DUNKIRK, N. Y.

"We have no better means of combating the cholera to-day than at any time since it became known to civilization, a thousand years ago," said a distinguished physician in a recent number of the *Review of Reviews*. The medical profession therefore stands confronted with the appalling fact that hitherto all theories of this disease have been so misleading, and all forms of treatment have proved so worthless, that longer to trust them would be little less than criminal. Better theories and practice are urgently demanded.

The bacillus theory of Dr. Robert Koch, which was so eagerly grasped at, is now found to be fallacious. Dr. Koch himself admits that comma shaped germs are found in the common diarrheas of summer everywhere, and he tells us: "Water, from whatever source, very frequently, not to say invariably, contains comma-shaped organisms." He is not ignorant of the fact that these bacilli are found in the secretions of the mouth and throat of healthy persons and in the dejections of hardened fecal matters. Dr. Koch also knows full well that Drs. Pettenkofer of Munich, and Emmerich of Berlin, two of the most distinguished members of the medical profession of to-day, and experts in this disease, drank each a cubic centimeter of "*culture broth*" containing these pathogenic bacilli without experiencing a single characteristic symptom of cholera, though the draught in each case was followed by liquid stools swarming with these germs. Hasterlik reports six cases of the same kind without any apparent results. The utter worthlessness of Dr. Koch's comma bacillus as diagnostic evidence of this disease is thus fully demonstrated.

As the result of a personal experience in every epidemic of this disease in our country since 1851, together with an experience of its effects upon my own person and a success in its treatment quite phenomenal, I am prepared to assert that cholera need be no longer the dread and scourge which hitherto it has been.

It is strange that a new philosophy of this disease which must revolutionize its theories and its treatment is now found where it never before has been sought for, but where alone it is possible to find it, viz. in the right interpretation of the symptoms which characterize the disease. This philosophy not only reveals the essential nature of this disease, but points unerringly to a more successful treatment.

The symptom of most vital importance, and the only one which is pathognomonic, is the watery exudations which find their way so profusely through stomach and intestines and skin. In fact, all other symptoms which follow this one have their origin *in it*, since, in the entire absence of *this*, neither of the others can have an existence. The most vital consequences, therefore, depend upon the right appreciation of this symptom, together with the promptness and efficiency with which its indications for treatment are carried out. This watery element is constituted of the serous element of the blood, and comes from every part and portion of the system.

The question now arises, by what process does this rapid separation of the finer element of the blood from the coarser take place? The nerves of the system, when in their normal condition, preside over and maintain the tonicity of every organ, vessel and tissue of the body. They control the functions and processes of every part. The rapid filtration of the watery element of the blood through the now loose and patulous walls of the blood vessels indicates a loss of tonicity on the part of the nerves which permeate those walls. On account of such weakened condition of the walls of the blood vessels a general serous outflow pours from every vein and venule of the body, and the great life current is thus robbed to supply these so-called rice water discharges. At the same time the weakened vessel-walls contract with diminished force upon their remaining contents, and consequently the brain and heart fail of an adequate supply, and the more fatal symptoms and death follow. Such is the secret of the disease and its rapid and phenomenal fatality.

The rapid abstraction of a single element of the blood becomes disastrous in the same manner as when the full blood itself is lost in the more common forms of hemorrhage. It is, therefore, passing strange that this rice water phenomenon never has been recognized as a hemorrhage, with all that such a hemorrhage implies. All symptoms and conditions incident to this disease, as also the changes observed upon the cadaver, are explainable upon the hypothesis of actual hemorrhage, and we are warranted in saying, *only* upon that hypothesis.

Owing to the failure to discriminate between the actions of the red corpuscles of the blood and its white discs, its chief constituents, this hemorrhage hypothesis has not been applied in explanation of this disease. The vital forces of the system depend largely upon the action of the red corpuscles, for through these chiefly are effected the oxygenation of the blood and the consequent revitalization of the system. A small loss of this element may become quickly fatal. On the other hand, the serum or white element which constitutes the bulk of the blood performs less vital functions, and its abstraction becomes neither so quickly nor so seriously manifest. In this disease enormous quantities are sometimes separated from the circulating current without fatal consequences.

Treatment.—Since the disease is essentially a neurosis, and its controlling symptom a hemorrhage, its treatment becomes at once clearly defined and the pure empiricism of the past must give place to a scientific treatment with vastly improved results. We must look upon the cholera hemorrhage as subject to the same general principles of treatment as other hemorrhages.

As the cholera hemorrhage occurs over so large a portion of the body, is colorless, and therefore virtually a *concealed* hemorrhage with all that is alarming which that word implies, it calls for attentions at once prompt, efficient and watchful. No painless diarrhea or painless vomiting is free from danger during a cholera epidemic, since the milder conditions of the disease often quickly change to those more grave and fatal.

Both the principles and the practice of medical science teach that position, *position*, POSITION, is the prime safeguard in sudden and profuse hemorrhages occurring from any cause. In the treatment of cholera hemorrhage, position with the body horizontal or with the head the lowest, is quite as indispensable as in that arising from any other cause.

Position in the treatment of cholera is not simply a repose in bed with the head resting comfortably upon the pillow, and raised or lowered at the pleasure or caprice of the patient, but to be efficacious, as in its graver cases, it must be *compulsory*, and strictly maintained, *as for the very life*, until the danger period is passed. The vital necessity of position in the treatment of cholera is shown by Murray, Cunningham and other distinguished authorities when they tell us that "once sitting upright in bed sometimes causes death in this disease." Not even in the act of evacuation of the bowels should the head be raised in the more serious cases. But position in this disease is sometimes difficult to secure, as the patient, when weakened by exhaustive discharges and pain, becomes disturbed in intellect and is with difficulty controlled.

If the best results are sought for, the horizontal position should be enforced in every case of even suspected cholera. In cases of great danger the body should be inclined with the head the lowest. This position should be maintained until the blood vessels contract upon their contents, which fact is shown by an improved condition of the pulse.

In the present condition of medical science, opium and its preparations stand far above other remedies which may be employed in the treatment of this disease. No remedy is known which surpasses this one in the power to change the perturbed condition of the nervous system and close up the diminutive avenues through which the watery element of the blood and the life ebb away together. During an epidemic it is hazardous to rely upon remedies taken through the mouth, since in cholera the action of the mucous membrane often becomes changed, so that internal remedies either fail to act or are ejected. Moments are sometimes precious, as a life may depend upon the certainty of retention of a remedy and the promptness and efficiency with which it may act. The hypodermic method is here our best resource. According to the reports of cases in Asia, Australia and elsewhere, the hypodermic use of morphia has shown almost uniformly favorable results, the one-eighth to the one-sixth of a grain of the latter very rarely need be exceeded or frequently repeated. Opium and morphia *in large doses* are decidedly contra indicated *in any of its stages*, since, if these drugs are retained in the stomach, they may become cumulative and in the case of reaction they might become fatal.

For the relief of the atrocious cramps, the administration of chloroform by inhalation, together with small doses of morphia hypodermically applied, offers the most speedy and effectual means at our command. The stimulation of the brain by currents of blood sent to that organ by *position*, wonderfully facilitates the control of the cramps.

For excessive thirst, ice may be given ad libitum; and if ice can not be obtained, the coldest water in small quantities and frequently repeated. The suffering from thirst in this disease is inconceivable, and it is unjustifiable, unmitigated cruelty to withhold these necessaries from the sufferer. Ice has been given freely in *every* case under my charge, and with the happiest effects.

The circulation should be promoted by the application of heat and friction to the extremities. Any further treatment may be conducted upon general principles.

En résumé. This disease, so destructive to human life, is thus found to be most simple in its character and positive in its indications for treatment. As a problem in medical science, cholera resolves itself into a question of supply of blood to the brain and heart. If this supply be kept up, a fatal termination to this disease is not probable. Whatever course will best promote this end, therefore, must secure the most favorable results in its treatment.

The inestimable value of *position* as the fundamental idea in the treatment of cholera was first exemplified upon my own person in 1854, and has been abundantly demonstrated in the epidemics which have since occurred.

The simple theory herein advanced is found in entire harmony with the highest principles and practice of the advanced medical science of to-day. It offers results such as never yet have been realized, and places within the reach of all a ready method of treatment. This treatment may be successfully employed even without the use of medicines.

In fine, in the light of the study of this disease during forty years, both at home and abroad, such as few have had either the opportunity or the inclination to pursue, and in view of the phenomenally favorable results of treatment based upon this philosophy, I believe myself fully warranted in asserting that the rate of mortality of this scourge may be reduced to less than half of that at which it confessedly stands to day.

The foregoing theories have been presented by the writer before the American Medical Association, the New York State Medical Societies and the Chautauqua County (N. Y.) Medical Society, also through the columns of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, the *Chicago Medical and Surgical Journal*, and the *Quarterly Epitome of Practical Medicine and Surgery*.

NECROLOGY

A Famous Irish Surgeon Dead—Dr. T. H. Parke, who Accompanied Stanley through Africa.—Dr. Thomas Heazle Parke, a distinguished surgeon, and one of Stanley's most intimate and beloved companions in the latter's trip across Africa in 1887–88–89, is dead. He was an Irishman, his birthplace being Ologher House, Drumona, County Tyrone. Dr. Parke was only thirty-six years old at the time of his death.

He was commissioned as surgeon in the medical staff of the British Army in 1881, and from that time onward his life was spent in active service abroad. The following year he was in the Egyptian campaign and received the Queen's medal and the Khedive's star. He then went through the cholera epidemic in 1883, and afterwards was in the Nile campaign for the relief of Gordon. Dr. Parke was present at the battle of Abu Klea, the action of Gubart and other engagements. He went across the Bayudu Desert in medical charge of the naval brigade under Lord Charles Beresford and returned in medical charge of the Guards camel corps under Lord Falmouth.

ACROSS AFRICA WITH STANLEY

Subsequently he crossed Africa with Stanley in 1887–88–89, and when he returned received many honors from societies, his government and the Khedive. He was put in command of a company of the detachment under Major Bartellot, which sailed up the Congo on the steamer *Stanley*. At one point of the journey, at Ipoto, Dr. Parke was practically in the power of the natives. He and his companions, separated from the main body, suffered severely from want of food.

In 1888, when at Fort Bodo, Stanley fell ill of sub-acute gastritis, he pulled him through After this he insisted upon accompanying Stanley to the Nyanza In the following year Dr Parke was himself stricken down But while suffering from fever he arose from his sick bed to minister to other invalids When Emin Pasha was found and met with his accident, Dr Parke attended him successfully

It is told of Dr Parke that when he found Lieutenant Stairs wounded by the poisoned arrow shot by the hostile natives of the Aruwimi forest, he sucked the poison from the wound

Stanley, in his work "In Darkest Africa," gives high praise to Dr Parke for his invaluable services and his fine character

Dr William Thomas White, editor for many years of the *New York Medical Register*, died September 17, 1893 He was born in Richmond, Maine, in July, 1829 He was a graduate of the New York Medical College in 1855, being a protegé and afterwards assistant to that other distinguished Maine man, the late Dr E R Peaslee He served as house surgeon to the Ward's Island hospitals for a time, going thence to the Isthmus of Panama as surgeon to the railroad He returned to New York after an absence of eight or nine years and at once identified himself with the Academy of Medicine, the American Medical Association and others of the best organizations He was secretary of the Academy, five years later, serving in that capacity for eight years He was an ex president of the Medico-Historical Society and Medical Association of New York County His positions on the staff of the Demilt Dispensary of the Presbyterian Hospital of Charity on Blackwell's Island and of the Veterinary Surgeons College, were well and honorably administered, and some of them were held down to the time of his demise Dr White's membership in the American Medical Association dates from 1866 He was one of the charter members of the great New York State Medical Association, now grown to a membership of 800, and the success of the body was very near his heart The cause of his death was referable to cardiac hypertrophy and its sequelæ

Dr Seth Rogers of Pomfret, Conn, died Aug 6, aged 70 years He was the twelfth son of a Vermont farmer and won his way into the medical profession by dint of perseverance, as well as a conflict with disabling ill health He was a man of Quaker parentage and an anti-slavery advocate before the breaking out of the war In 1862, he took the office of surgeon to a colored regiment organized by Col Thomas W Higginson, the First South Carolina Volunteers His medical education was partly obtained at the New York University and partly at the Castleton school He also studied for a time in Paris under Trousseau and Valleix He visited South America in 1858 for the sake of his health Worcester, Mass, was his home during the earlier years of his career In 1863, he was obliged by illness to leave the army, and he went to Pomfret in order to follow an outdoor life on a farm He was able to establish a winter practice in Florida for a dozen years, and cared for patients at his own house in Pomfret during the summer months Although his life was one long conflict with the *res augusta domi* and with ill health, he was a character of so much vitality and courage that he has left a record bright with honorable accomplishment

Dudley S Brainard, died at Osage, Iowa, Saturday, Sept 9, 1893 Dr Brainard was born in Williamsburg, N Y, now a part of Brooklyn, Jan 3, 1851, and came to Wisconsin with his parents in 1861 six years later they removed to Zumbrota, Minn He received his medical education at the University of Buffalo, N Y, graduating Feb 23, 1875 After practicing a short time in Minnesota and Wisconsin he removed in 1879 to Stacyville, Iowa, where he resided until a short time before his death

Dr Brainard prized his profession highly and was regarded as one of the strongest men in regular medicine in Northern Iowa At the time of his death he was a member in good standing in the county, State and American Medical Associations He was a faithful attendant at the meetings of these societies contributing frequently papers, which were listened to with interest

Dr Brainard was married in 1876, and his estimable wife and two children survive him

His memory will long be held in loving esteem among those who knew him as a faithful physician, a loyal friend, a noble man, and a Christian

Dr Edwin N Colt of Brooklyn, died on the 15th inst, after a period of sixty years of almost uninterrupted family practice He was the *doyen* of the medical faculty of his town, and it is said that there are only two survivors in New York State whose dates of graduation antedated that of Dr Colt He was a native of Berkshire County, Mass, having been born there on August 7, 1811 He was a graduate of the old Berkshire school in the year 1832 He was highly honored by the community in which he lived

Dr Philemon Hommell of Jersey City died suddenly September 14, aged 57 years He was an Alsatian by birth and a Parisian by education He studied pharmacy at Paris and became the pharmacist to the Hôtel Dieu, following his father and grandfather in the first choice of a profession Having come to America, circumstances led him to study medicine and about 1882 he obtained his doctorate He was successful in practice, and at the time of his death was a visiting physician to the Jersey City Hospital His death was due to pulmonary hemorrhage

Dr Austin K Gould of Worcester, Mass, died Sept 9, aged 67 He was in the volunteer medical corps during the war of the rebellion as surgeon

He was placed in charge of one of the division hospitals at Wilderness Run Here he was captured by the confederates and for nine months languished in the prisons of Andersonville, Florence and Charleston

In the latter place he was for nine days under a continual fire from the Union batteries

Prof Lyman Bartlett How, M D, of Manchester, died in Hanover, N H, Sept 15 of consumption He graduated from Dartmouth in 1860, and from the medical department in 1863 He had been Professor of Anatomy at Dartmouth for twenty-five years, and held the place until this year, when failing health compelled him to give it up Dr How was 55 years old, and leaves a widow and two children

Dr Horatio Nelson Page of Chelsea, Mass, aged 87 years died on the 16th at the residence of his son-in-law, Charles E Reed, in Milwaukee Dr Page was well known in the East, having practiced at Chelsea and Bangor, Me, for many years

Dr Joel Henry Cooper, father of Congressman H A Cooper died at his home in Burlington, Vt, aged 70 years He was born in Windsor County, Vt, and went to Burlington in 1845, practicing medicine until his retirement about ten years ago

Dr W H Galt, health officer of the city of Louisville for the last twelve years, died suddenly Sept 14, of "blood poisoning" He was 66 years of age and one of the best known physicians in the State

Dr E F Long, past grand master-at-arms of the Knights of Pythias of Wisconsin, died Sept 8, at his home in Black River Falls, Wis, after a prolonged illness

Dr Frank W Brown, of 51 Eliot Street, Detroit, Mich, died Sept 9 He was a son-in-law of the late John J Bagley and his father was a physician of that city

Dr William P Buck, who was surgeon of the old Eighth Illinois Infantry during the war, died Sept 15 at his home at Mowequa, Ill

Dr Abram Simmons of Cohoes, N Y, died at that city on the 12th

Dr John L Galliver of Toledo, died Sept 18, 1893

Dr Edward Warren Bey of Paris, died in that city Sept 16

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.
SUBSCRIPTION PRICE, INCLUDING POSTAGE.
PER ANNUM, IN ADVANCE $5.00
SINGLE COPIES 10 CENTS.
Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE., CHICAGO, ILLINOIS.
All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

SATURDAY, SEPTEMBER 30, 1893.

THE SEASON OF THE STUDENT.

Let those study who never studied before.
Let those who always studied, now study the more.

The annual pilgrimage of the medical students has commenced; some returning from summer semester with renewed health and vigor, others fresh from academy in pursuit of a new branch of science, and all classes full of enthusiasm and bold resolve. The dingy old college looks well to these youths, for in its walls are stored the paraphernalia of the amphitheater, the laboratory and the clinique. Even the musty jokes of the professors seem to have penetrated the cracks and crevices about the lecture rooms, which seem to be smiling softly to themselves as the eye of the neophyte rests upon them.

But no one better than the medical student, knows that there is a serious side to his life. He may have a rollicking, devil may-care expression at the beginning of the term, but he knows that there are pains and penalties as well as prizes on examination days, and the former are as two to one.

The student has changed from the days of fifty years ago. Then, as a rule, he forsook the plow to follow a preceptor for six months immediately preceding the opening of the college term. He kept calls, studied anatomy in a desultory way, and occasionally assisted his preceptor in important cases. He then came to college with a fair knowledge of the routine life he intended to lead, he listened to many daily orations through the allotted period, and in a very short time received the engrossed parchment that authorized him to respectively save or slay according to his ability on the one hand, or blundering propensities on the other. Those days have passed for the American student; he may have less native keenness than his predecessor, but he has vastly more collateral knowledge. He is compelled to show evidence of previous academical study upon entrance, and there is a strong probability that should he cut the recitation room, he will be necessarily absent on Commencement Day.

The pedagogue, too, has changed with the times; he no longer cultivates oratory, but the details of the branch intrusted to him; his speech is seldom studied, but his ideas are those born of intimate study of the subject in hand, and more than that, the fruit of a greater experience than that of his predecessors. The great increase in population has multiplied hospitals and dispensaries, until there is now little lack of opportunity for study of actual cases of any particular affection. The scientific pedagogue endeavors to allure and attract the students by class experiments and demonstrations. These have taken the place of the anecdotes that were used by all the old time professors. Our student must have his knowledge completely digested by the end of the term, so thoroughly mixed and incorporated into himself that it is his own. If he disgorges it whole, in the examination room, he will be through life a mental dyspeptic. The thorough assimilation of the knowledge poured into him also stimulates originality. "Bees," says MONTAIGNE, "cull their several sweets from this flower and that blossom, here and there where they find them, but afterwards themselves make the honey, which is all and purely their own, and no longer thyme and marjory." The modern method of teaching seeks to instil in the mind of the student the general principles of sincerity of purpose, attention to the lecturers and demonstrators; and a true student will learn modesty from the history of the art. The student also soon learns that cultivated eccentricities of manner and speech are no longer a passport to the highest standing in his class. He will gain much from the diversity of opinions he may hear expressed in the lecture rooms, and if he be wise he will follow the opinions that seem founded on reason. He will remember that the Republic of letters is a Republic and not a kingdom; for there is no king. He only commands who has reason on his side.

Few departments of the medical college are more useful than the quiz, which is not only invaluable to the student, but is made use of by the instructor to gauge the capacity of his pupils; as a young horse is brought out and exercised by his trainer, that the one may be made faster and stronger by exercise, and the other may know his gait, speed and peculiarities. But the quiz master should be entertaining and engaging in manner; the quiz "driver" is an unmitigated nuisance.

The student, to be successful, must avoid excesses, keep healthy and pay due attention to exercise while storing his mind; remembering the saying of PLATO that one must form not only a mind, and not only a body, but both a mind and a body, to become a MAN.

THE AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION

No greater evidence of the altered position of electricity as a remedial agent need be sought than the character of the attendance and discussions at the recent meeting of the Association in Chicago The interested participants seemed equally divided between those who were avowed specialists of National reputation and those whose standpoint was that of the general practitioner, and it was easy to see that both the speakers and hearers appreciated the educational value of the occasion The two days' discussion on the character of coils, induced currents, and the new sinusoidal currents produced by specially constructed dynamos, and as well the discussion on fibroid tumors and individual papers showed scientific qualities unsurpassed in any other National organization It showed also that such technical, though practical, subjects could not be adequately considered in any other medical organization than one devoted to electro therapeutics or in a special section of our own great ASSOCIATION

The organization of this Association was due to the combined labors of BETTON MASSEY, GOELET and WM JAMES MORTON, names all standing for what is best in the newer electro-therapeutics To them the profession are indebted for this most important step in the rescue of electro-therapeutics from empiricism and the ascertainment of a scientific basis for its claims

Blatant quackery had already been relegated to as quiescent a position as the ever-gullible public will permit, but the work cut out for an association devoted to medical electricity was even more difficult, it was the rescue of the remedy from the hands of its avowed friends—men who intrusted a noble agency to unskilled assistants and nurses REMAK, ERB and DUCHENNE DE BOULOGNE builded well the foundation of modern electro-therapeutics, but so much can not said for CHARCOT, who, great as he was, was responsible for a school of "impressionists" largely recruited among French and American neurologists, whose influence was distinctly inimical to scientific electro-therapeutics

To APOSTOLI is due the modern revival of the physical methods of ERB, and as the field of their application now invaded gynecology and other departments capable of direct study and materialistic demonstration, it became finally possible for the questions involved to be discussed by believers in mere natural phenomena rather than mysticists

As physical questions, involving the application of measured quantities and known qualities of an important force of nature, the subjects discussed at the three meetings of the Association have proved themselves sufficiently attractive to draw large audiences, and the discussions have been particularly full and exhaustive In accord with recent tendencies much space was devoted to gynecological questions, though it may possibly surprise some surgeons not present to notice that the contra indications of electricity as contrasted with surgery received marked notice

The JOURNAL has recognized the importance of these demonstrations of advanced electro-therapeutics from the first, having been the only publication to receive and publish the full proceedings of each meeting, and we take pleasure in announcing the early appearance of the transactions of the recent meeting in forthcoming numbers, together with other contributions from time to time, relating to this interesting field of research

CHOLERA

At no time since the introduction of cholera into Europe in 1829, were there so many infected points as at present This is no doubt owing to the greater facilities of communication, while it is also true the number of cases and the mortality incident to the progress of the disease is not as great as heretofore, the necessary result of greater precaution taken to prevent the spread of the same Cholera is abating in Russia in the districts where for the last two years it has raged with such fatal results, while at St Petersburg, the Crimea, and a few ports on the Black Sea it is on the increase and will no doubt continue so for some time Cases are also reported at Constantinople, and for the first time in Servia Cairo in Egypt is also said to be infected

In Galicia and Hungary the disease still prevails, while the epidemic is decreasing at the Danube ports in Roumania, with the exception of Brahjlon, where the fresh cases and deaths are about the same as for the last three weeks There is not much change at Rome, Genoa, Leghorn and Naples At Budapest there is an increase, also at Vienna In both Budapest and Vienna, cholera is spreading among the better classes At New Keltendorf, near Vienna, a man died of cholera, whose illness is said to have been caused by drinking water from the Danube

A panic has been created at Bilboa on the Bay of Biscay in Spain, by the breaking out of cholera and it is rapidly spreading to the surrounding country At Baremme, a village of 1,000 inhabitants in the Basses Alps in Southeastern France a very violent outbreak has occurred

There has been a decided increase at Brest, Quimper and various other places in Western and Northwestern parts of France, with an increase in the number of infected localities In Belgium, cholera is rapidly spreading in Damperemy, Marchieniess and Aupont, small towns in the province of Hainut

A workman is reported to have cholera at the Hague This is the first case There is not much change in the situation at Berlin or throughout the

German Empire, with the exception of Hamburg Here the disease has again broken out after an exemption of nearly five months This is significant, as we may expect a like occurrence elsewhere It is attributed to a break in the pipes that allowed water from the river Elbe to mix with the pure water (After so long an exemption the question naturally arises how long may streams be polluted by the cholera poison?) Is it not possible that other causes may have had to do with the fresh outbreak? All the cases and deaths reported were in the suburbs of the city One case occurred aboard the Rotterdam steamer *Amsdel* which has been lying in the harbor since September 16 It is also reported that cholera has appeared in the military barracks at Eppendorf a suburb on the Alster River Complaint has been made that the cases were not announced earlier and that the water supply was not all filtered In consequence of this outbreak the Hamburg-American Steamship Company have decided to dispatch their vessels hereafter from Cuxhaven Steerage passengers for America will be kept five days under medical control at Cuxhaven before embarking The stopping of the *Augusta Victoria* at Southampton to await the arrival of a medical inspector from Hamburg, was owing to the fact that one of the crew was suffering from choleraic disease It is announced that if any cases should occur before reaching the port of New York she is to return to Southampton without making a landing It is also stated that the water supply of Hamburg has been examined and found to be pure For the last two weeks deaths by cholera at eight different points in England have been reported, the most serious outbreak being that at Hull The indications are that the disease is slowly spreading in England, although owing to the care taken no serious outbreaks have occurred The following cable will explain itself

> LONDON, Sept 19—Further questions were asked in the House of Commons to-day regarding the presence of cholera in Great Britain In reply to these questions the Rt Hon Henry Fowler, president of the Local Government Board, stated that, with the exception of three ports on the east coast, all the ports of Great Britain were free from cholera There was not the slightest reason, he added, to suppose that there was an epidemic of Asiatic cholera in any part of the United Kingdom No cholera cases had occurred at Southampton The medical experts attached to the Local Government Board held that there was no danger of infection from a ship that had been out fourteen days from Great Britain, and which had a clean bill of health

Where from and how did the three ports on the east coast become infected? Was it water-borne or brought by vessels to these places, carrying immigrants from the continent for transshipment by way of Liverpool to the United States? Unless the baggage of the steerage is thoroughly disinfected, might there not be danger, even if the vessel had a clean bill of health and had been out from Great Britain fourteen days? From the foregoing it will be seen that, owing to the many points of infection and their daily increase, there is still danger of the introduction of cholera into the United States this season While it is true that, owing to the extraordinary efforts that have been made, we have been so far spared, it is also safe to assume that the present pandemic will continue for the next season in Europe Why not, then, suspend immigration?

In this connection it will not be out of place to call attention to the announced discovery at Berlin of a new bacillus which is claimed to have more to do with cholera than the comma bacillus of KOCH, also to a repetition of PETTENKOFER'S and EMMERICH'S experiment as follows

> VIENNA, Sept 20—In the Institute of Experimental Pathology here, Professors Hasterlik and Stockmayer, four students and others swallowed a quantity of comma bacilli They suffered no bad effects beyond headache and nausea Professor Stricker therefore draws the conclusion that the comma bacilli will not cause cholera in the case of strong, healthy subjects

THE POISON OF RESPIRATION

Some recent experiments by RAUER, *Untersuchungen uber die Giftigkeit der Expirationsluft*, detailed in the *Zeitschrift für Hygiene und Infectionskrankheiten*, tend to deprive the organic matter of respired air of the importance hitherto attached to it as a morbific agent Carbonic anhydrid has always been recognized as deleterious when present in large percentages in the air which enters the lungs It is the deadly "after damp" of the mines, and many opportunities unfortunately have been afforded of determining the postmortem appearances in death from the inhalation of this gas We are, therefore, not surprised to find that RAUER'S mice died in an atmosphere in which the carbonic acid produced by the mice themselves amounted to 15 5 per cent because for every per cent so produced an equivalent amount of oxygen was used up, thus reducing the available oxygen to 5 5 per cent Nor are we surprised that they lasted longer but eventually died in a free supply of an atmosphere containing 15 5 per cent of introduced carbonic acid, although the available oxygen of the mixture was 17 5 per cent We have, however, been accustomed to regard the relatively small proportion of carbonic acid in the vitiated atmospheres of overcrowded rooms as in itself comparatively harmless, and to consider that its quantitative determination by the sanitary chemists was of interest only as a measure of the associated organic elimination from the lungs, to which the headache and prostration attending the breathing of such air are usually attributed It is true that R ANGUS SMITH found 3 per cent of carbonic acid to enfeeble the heart and quicken the respiration even to gasp He claimed also that these effects could be det with even 1 per cent, but as he himself fai recognize such effects in the 2 per cent, of the

THE AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION

No greater evidence of the altered position of electricity as a remedial agent need be sought than the character of the attendance and discussions at the recent meeting of the Association in Chicago The interested participants seemed equally divided between those who were avowed specialists of National reputation and those whose standpoint was that of the general practitioner, and it was easy to see that both the speakers and hearers appreciated the educational value of the occasion The two days' discussion on the character of coils, induced currents, and the new sinusoidal currents produced by specially constructed dynamos, and as well the discussion on fibroid tumors and individual papers showed scientific qualities unsurpassed in any other National organization It showed also that such technical, though practical, subjects could not be adequately considered in any other medical organization than one devoted to electro-therapeutics or in a special section of our own great Association

The organization of this Association was due to the combined labors of Betton Massey, Goelet and Wm James Morton, names all standing for what is best in the newer electro-therapeutics To them the profession are indebted for this most important step in the rescue of electro-therapeutics from empiricism and the ascertainment of a scientific basis for its claims

Blatant quackery had already been relegated to as quiescent a position as the ever-gullible public will permit, but the work cut out for an association devoted to medical electricity was even more difficult, it was the rescue of the remedy from the hands of its avowed friends—men who intrusted a noble agency to unskilled assistants and nurses Remak, Erb and Duchenne de Boulogne builded well the foundation of modern electro-therapeutics, but so much can not be said for Charcot, who, great as he was, was responsible for a school of "impressionists" largely recruited among French and American neurologists, whose influence was distinctly inimical to scientific electro-therapeutics

To Apostoli is due the modern revival of the physical methods of Erb, and as the field of their application now invaded gynecology and other departments capable of direct study and materialistic demonstration, it became finally possible for the questions involved to be discussed by believers in mere natural phenomena rather than mysticists

As physical questions, involving the application of measured quantities and known qualities of an important force of nature, the subjects discussed at the three meetings of the Association have proved themselves sufficiently attractive to draw large audiences, and the discussions have been particularly full and exhaustive In accord with recent tendencies much space was devoted to gynecological questions, though it may possibly surprise some surgeons not present to notice that the contra indications of electricity as contrasted with surgery received marked notice

The Journal has recognized the importance of these demonstrations of advanced electro-therapeutics from the first, having been the only publication to receive and publish the full proceedings of each meeting, and we take pleasure in announcing the early appearance of the transactions of the recent meeting in forthcoming numbers, together with other contributions from time to time, relating to this interesting field of research

CHOLERA

At no time since the introduction of cholera into Europe in 1829, were there so many infected points as at present This is no doubt owing to the greater facilities of communication, while it is also true the number of cases and the mortality incident to the progress of the disease is not as great as heretofore, the necessary result of greater precaution taken to prevent the spread of the same Cholera is abating in Russia in the districts where for the last two years it has raged with such fatal results, while at St Petersburg, the Crimea, and a few ports on the Black Sea it is on the increase and will no doubt continue so for some time Cases are also reported at Constantinople, and for the first time in Servia Cairo in Egypt is also said to be infected

In Galicia and Hungary the disease still prevails, while the epidemic is decreasing at the Danube ports in Roumania, with the exception of Brahjlon, where the fresh cases and deaths are about the same as for the last three weeks There is not much change at Rome, Genoa, Leghorn and Naples At Budapest there is an increase, also at Vienna In both Budapest and Vienna, cholera is spreading among the better classes At New Keltendorf, near Vienna, a man died of cholera, whose illness is said to have been caused by drinking water from the Danube

A panic has been created at Bilboa on the Bay of Biscay in Spain, by the breaking out of cholera and it is rapidly spreading to the surrounding country At Baremme, a village of 1,000 inhabitants in the Basses Alps in Southeastern France a very violent outbreak has occurred

There has been a decided increase at Brest, Quimper and various other places in Western and Northwestern parts of France, with an increase in the number of infected localities In Belgium, cholera is rapidly spreading in Damperemy, Marchieniess and Aupont, small towns in the province of Hainut

A workman is reported to have cholera at the Hague This is the first case There is not much change in the situation at Berlin or throughout the venienced as possible Then, is it lawful to build a sanitarium for the cure of the sick or to bathe in the waters those afflicted with disease? It is certainly lawful to do so, continues the court, provided the sanitarium is properly conducted and well managed, so as to do no injury to any person which reasonably and with due care can be avoided This being true, it follows that those who, with due care, use the water of an artesian well to bathe patients at a sanitarium, the well and sanitarium being on their own premises, are not liable to an adjoining owner for allowing the water, so polluted, to flow into a stream which is the natural water course of that section Moreover, if the person complaining stood by while money was being expended in erecting such sanitarium, and acquiesced for more than a year in the flow of water, he could not, on account of the law of estoppel, enjoin the continued operation of the sanitarium

Mississippi Valley Medical Association —Special car for physicians will leave the new Illinois Central R R station, 12th Street and Michigan Avenue on Tuesday evening at 11 30, by the "Big 4" route, reaching Indianapolis at 7 A M Fare for the round trip, one and one-third excursion rate The sleeping-car will be at the depot at 9 30 P M for such as wish to retire earlier than 11 30 Engage sleeper and buy tickets at the Big Four office, No 234 Clark Street

SELECTIONS

Report of the British Local Government Board, 1891-92 —The supplement to the twenty-first annual report of the Local Government Board, 1891–92, containing the report of the medical officer, has just been received Dr R Thorne Thorne, who now occupies this important position under the British Government, begins his report with a testimonial to the distinguished services of his predecessor, Sir George Buchanan, who resigned March, 1892 "For over thirty years," he says, "Sir George Buchanan has, either as medical inspector or as the Board's medical officer, contributed to the annual reports of the medical department, and many of his contributions have become classic in the literature of public health both in this and in other countries But those alone who have had the opportunity and pleasure of working under his direction can appreciate to the full the important influence for good which his labors have had, and they alone can realize how much the medical department owes to the example which he set, as an earnest worker and director who never ceased to claim that all true sanitary progress must be based on accurate and scientific research into the etiology of disease " Sir George Buchanan was a worthy successor to Sir John Simon, whose name is a household word in the annals of public health

An interesting account is given by Dr Bruce Lowe of an anomalous illness that prevailed in Northamptonshire characterized by pneumonia, sometimes by meningeal symptoms, and frequently associated with tonsilitis or sore throat Certain of these cases had much in common with sporadic cases of cerebro-spinal fever that prevailed in some of the Eastern counties during the previous year

An outbreak of scarlet fever at Enfield and Edmonton, investigated by Dr S Monckton Copeman, was attributed to a milk supply which was derived from a farm at some distance from Essex, where attacks of the same disease occurred among consumers of milk from the same farm No infection of the milk from a human source could be made out, but the cows were found to be suffering from udder eruption Inoculation of calves with matter from this eruption gave negative results in the hands of Dr Klein In cultures on gelatin a non liquefying microbe was the predominant organism, similar to the streptococcus isolated by him from sores on Hendon cows in 1885, but the present organism inoculated into mice proved only doubtfully pathogenic

Complaints of nuisance and of injury to health from the transportation of town manure to agricultural districts led to an investigation and an exhaustive report on the subject The complaints had reference chiefly to manure from London, although that from other large towns as Liverpool, Newcastle, Nottingham, Portsmouth and Plymouth, had also been complained of in the districts to which it is distributed London manure is as a rule entirely free from human excreta, but it is otherwise a compound of nearly every form of animal and of some forms of vegetable refuse, such materials as dead and putrefying animals, fish guts, paunches etc., being mingled with stable manure, cabbage stalks, rotten vegetables, etc And the diseases which were most commonly regarded as being referable to the offensive emanations were diphtheria and allied sore throat Two principal objects were held in view during the inquiry To learn how far allegations as to injury to health and even as to the production of infectious diseases were supported by actual experience and to ascertain how far nuisances, owing to the unloading and temporary deposit of the manure at railway sidings and elsewhere the lack of care in carting could be dealt with by further regulations The outcome of the inquiry under the first heading showed that in so far as bodily discomfort and functional disturbance, at times involving general impairment of health, are concerned, exposure more or less recurring to the offensive effluvia concerned does affect health and that whilst certain affections, such as sore throat, which it has not always been possible to differentiate from diphtheria can with some degree of certainty be held to have relationship with exposure to the manure effluvia, it has not been possible so to eliminate other sources of infection and of disease as to identify the effluvia with the production of any specific affection To a great extent the nuisances arising from the manure traffic are already under the control of local authorities through the provisions of the Public Health Acts or through by-laws which may be made thereunder but in agricultural districts and small market towns there is often an indisposition on the part of local authorities to exercise the powers which they possess in this connection

The supplement contains a further report on the pathology and etiology of diphtheria by Dr Klein Taking the presence of the Klebs-Loffler bacillus in definite relation with the mucous membrane as the vera causa of diphtheria he tested various throat ailments with the following results "Scarlatinal diphtheritis" occurring in the early days of scarlatina is not, judged from the bacteriological standpoint, diphtheria, but similar manifestations whether of diphtheritic or croupy type, occurring in the later stages of and during convalescence from scarlet fever, are almost invariably true diphtheria He found also that membranous croup of the larynx or trachea, although altogether dissociated clinically from diphtheria, must be regarded as essentially that disease

Dr Klein's experiments on the inhibitory action of the metabolic products of one microorgan

pro-water factories, the organic matter of the respired air again assumed importance as the most deleterious of the excreta of respiration

Now, however, comes **RAUER** with mice unharmed by the products of respiration, provided the carbonic acid be removed He considers it proved by his experiments that there is no other poison produced by the breathing of animals than the carbonic acid, that indeed the existence of an organic poison in the air exhaled is impossible, for when the carbonic acid was removed there was no injurious effect, and a mixture of artificially produced carbonic acid had the same effect as that produced by an air of respiration containing the same proportion of carbonic acid With the exception of this acid there is no gaseous poison liable to be effective in small quantities evolved from men or animals, and the conclusion is reached that men may live in absolute health in rooms with defective ventilation

Without questioning the accuracy of these experiments we are inclined to offset them with the grand experiment that has been made during the past half century by medical men, sanitarians and philanthropists in increasing the air space and ventilation in prisons, tenements, barracks, emigrant and other ships, and living rooms generally, with the result of banishing the deadly typhus which the accumulated experience of generations recognized as due to the aggregation of human beings in confined and unventilated quarters **RAUER**'s experiments are interesting, but the other is more convincing

RIGHT TO MAINTAIN SANITARIUMS WHICH POLLUTE NEIGHBORING STREAMS

Hospitals and homes for the sick are recognized as lawful institutions, to be fostered and encouraged, and not to be discouraged or repressed But now comes the novel and important question as to whether one who sinks an artesian well upon his own land, and uses the water to bathe the patients in a sanitarium or hospital erected by him on the premises, is liable to injunction and damages for allowing the water to flow into a stream which is the natural water course of the basin in which the artesian well is situated, the owner being free from negligence or malice, and using all due care in avoiding injury to his neighbor This was exhaustively considered by the Supreme Court of Indiana in the case of Barnard v Shirley, decided June 6, 1893, reported in the advance sheets of 34 "Northeastern Reporter," 600 No principle of law is better settled, it is said, than that a man has the right to the lawful use and enjoyment of his own property, and that if, in the enjoyment of such right, without negligence or malice, an inconvenience or loss occurs to his neighbor, it is a wrong for which there is no liability If, in the excavation of his land, he should uncover a spring of water, salt or fresh, acidulated or sweet, he will certainly not be obliged to cover it again, or to conduct it out of its course, lest the stream, in its natural flow, may reach his neighbor's land But on the main point involved here, the nearest precedent is found in a mining case, where it was held that in the operation of mining in the ordinary and usual manner, a person may, upon his own lands, lead the water which percolates into his mine into the streams which form the natural drainage of the basin in which the mineral is situate, although the quantity as well as the quality of the water in the stream may thereby be affected And this doctrine has been adopted by the court in this case, where the contention was that water caused to rise from the earth was polluted in bathing the bodies of diseased persons, having all manner of diseases, including syphilis, which after it had thus become befouled, was caused to be conveyed in a tile ditch underground, to the adjoining lands over which it was made to flow into a natural stream of water running thereon, causing such natural stream of water to become befouled and polluted, thereby exposing the same to the stock pasturing and feeding upon said land where stock was accustomed to run, feed, and pasture, such as milch cows, horses and hogs, which drank the water in its befouled and polluted condition The court said that the natural right to have the water of a stream descend in its pure state must yield to the equal right of those above Their use of the stream for the manifold purposes for which they might lawfully use it would tend to render it more or less impure The water might thus be rendered unfit for many uses for which it had before been suitable, but, so far as that condition may result from reasonable use of the stream in accordance with the common right, the lower riparian proprietor has no remedy Sewage and waste material may be cast into streams if material injury is not thereby caused Inconveniences resulting from many causes must be endured by individuals for the general good otherwise we should have to forego a multitude of the blessings of modern civilization

Still, when a business is dangerous, unhealthful, or otherwise greatly injurious to a community or to an individual, and it is possible to avoid the injury by a more careful management, or even, if necessary, by a removal to a more secluded or less objectionable place, then the owners of the noxious business will be mulcted in damages, and, if necessary, restrained by the courts And a man may not carry on a business which poisons the air and renders it unhealthy in a thickly populated neighborhood, and especially in the center of a large city So establishments which involve danger, as powder mills and certain kinds of manufactories, must seek a secluded place where as few persons may be inconvenienced as possible Then, is it lawful to build a sanitarium for the cure of the sick or to bathe in the waters those afflicted with disease? It is certainly lawful to do so, continues the court, provided the sanitarium is properly conducted and well managed, so as to do no injury to any person which reasonably and with due care can be avoided This being true, it follows that those who, with due care, use the water of an artesian well to bathe patients at a sanitarium, the well and sanitarium being on their own premises, are not liable to an adjoining owner for allowing the water, so polluted, to flow into a stream which is the natural water course of that section Moreover, if the person complaining stood by while money was being expended in erecting such sanitarium, and acquiesced for more than a year in the flow of water, he could not, on account of the law of estoppel, enjoin the continued operation of the sanitarium

Complaints of nuisance and of injury to health from the transportation of town manure to agricultural districts led to an investigation and an exhaustive report on the subject The complaints had reference chiefly to manure from London, although that from other large towns as Liverpool, Newcastle, Nottingham, Portsmouth and Plymouth, had also been complained of in the districts to which it is distributed London manure is as a rule entirely free from human excreta, but it is otherwise a compound of nearly every form of animal and of some forms of vegetable refuse, such materials as dead and putrefying animals, fish guts, paunches etc, being mingled with stable manure, cabbage stalks, rotten vegetables, etc And the diseases which were most commonly regarded as being referable to the offensive emanations were diphtheria and allied sore throat Two principal objects were held in view during the inquiry To learn how far allegations as to injury to health and even as to the production of definite diseases were supported by actual experience, and to ascertain how far nuisances, owing to the unloading and temporary deposit of the manure at railway sidings and elsewhere, and lack of care in carting could be dealt with by law or regulations The outcome of the inquiry under the first heading showed that in so far as bodily discomfort and functional disturbance, at times involving general impairment of health, are concerned, exposure more or less recurring to the offensive effluvia concerned does affect health, and that whilst certain affections, such as sore throat, which it has not always been possible to differentiate from diphtheria, can with some degree of certainty be held to have relationship with exposure to the manure effluvia, it has not been possible so to eliminate other sources of infection and of disease as to identify the effluvia with the production of any specific affection To a great extent the nuisances arising from the manure traffic are already under the control of local authorities through the provisions of the Public Health Acts or through by-laws which may be made thereunder, but in agricultural districts and small market towns there is often an indisposition on the part of local authorities to exercise the powers which they possess in this connection

The supplement contains a further report on the pathology and etiology of diphtheria by Dr Klein Taking the presence of the Klebs-Loffler bacillus in definite relation with the mucous membrane as the *vera causa* of diphtheria he tested various throat ailments with the following results 'Scarlatinal diphtheritis" occurring in the early days of scarlatina is not, judged from the bacteriological standpoint, diphtheria, but similar manifestations whether of diphtheritic or croupy type, occurring in the later stages of and during convalescence from scarlet fever, are almost invariably true diphtheria He found also that membranous croup of the larynx or trachea, although altogether dissociated clinically from diphtheria, must be regarded as essentially that disease

Dr Klein's experiments on the inhibitory action of the metabolic products of one microorganism on the life pro-inclined to consider morphœa and scleroderma as distinct affections, while European authorities are rather inclined to the opposite view

The author has not attempted to advance any original suggestions regarding treatment, contenting himself with the clinical presentation of the case

Dr W A Hardaway of St Louis, Mo, read a paper entitled

A CASE OF TUBERCULOSIS OF THE SKIN SIMULATING LUPUS ERYTHEMATOSUS

The patient was a pharmacist, 28 years of age, previous health good, family history good and no history of tubercle Tall and spare, and of sallow complexion, yet he is a man of great endurance In May, 1892, he noticed on his left malar region a small yellowish elevation the size of a pinhead This was supposed to be a flesh worm and was squeezed, blood only being thereby obtained The lesion gradually enlarged peripherally, becoming hard and red No subjective phenomena He came under Dr Hardaway's care in June, 1892, the lesion being now as large as a dime, presenting an atrophic whitish center surrounded by a slightly raised infiltrated border of a dull red color The lesion was anæsthetic, a characteristic which has been noticed in tubercular syphilides The anæsthesia was temporary In a short time the patient passed from under observation and was gone for a month, during which time he was thoroughly treated for syphilis by another physician The treatment simply aggravated the general and local conditions September 3, 1892, the original lesion was the size of a half dollar, not raised from the surface and moderately infiltrated The center is still atrophic, and the same narrow dull red line presents at the borders In a few weeks several small acniform pustules appeared on the right temple, side of the nose, and inferior angle of the right eye Others presented on the end of the nose, right ala, and left cheek These lesions were not painful or itchy Each lesion was surrounded by a red areola which subsequently extended and became infiltrated, crusts forming over the centers of the lesions The crusts were fatty or sebaceous in character, and with a dull red surface beneath were suggestive of lupus erythematosus As the borders of the lesions extended the centers cicatrized, presenting the same dirty yellow appearance of the original patch December 9, thiosinamin was given hypodermically at 12, and the patient stated that about 7 P M the patches became hot and red, remaining so for an hour or two Other injections of the drug were subsequently given but without effect December 22, the lesion in the right eye had become as large as a quarter of a dollar Electrolysis had been tried on the spot on the left temple, but it was still spreading A new spot was now found on the chest, beginning like an acne papule, which became postulated and finally scaly This went through the same metamorphosis as the previous lesions, the elevated red border extending until the lesion was as large as a pea, when it was thoroughly destroyed by electrolysis Early in January a small piece of skin was excised from the lesion on the right temple and examined microscopically Electrolysis was tried upon the other lesions with an apparent cure, followed by a relapse after a few months, manifesting itself first by the formation of a scale in the center of the scar Electrolysis was persisted in as fast as the spots appeared and with apparent success In March a small patch similar to the others appeared upon the scalp, this is now the size of a dime The tendency to peripheral extension throughout has been a marked feature in this case The whole nose finally became involved and became a continuous lesion of partly red and partly cicatrized integument, presenting a striking likeness to some forms of lupus erythematosus Dr Hardaway thought that this resemblance would have been more striking if the patches on the side of the face had been allowed to coalesce instead of being destroyed by electrolysis At no time could nodules of lupus vulgaris be demonstrated, nor were the sebaceous plugs of lupus erythematosus seen at any time The patient's general health has continued so poor that at one time general tuberculosis was considered imminent A trip to Colorado brought about great improvement At last accounts the disease was apparently quiescent, the patient's general health good, and no lesions of the lungs and larynx have been detected Dr C Heitzmann reports, after microscopical examination of the excised piece of skin, that a moderate number of tubercle bacilli were found A large number of inflammatory corpuscles were also detected, displacing the fibrous connective tissue Nests of inflammatory corpuscles were seen in the arrangement characteristic of tuberculosis The diagnosis was local tuberculosis of the skin, which was entirely in accord with the clinical diagnosis

Dr H R Crocker of London, Eng, read a paper on

LUPUS ERYTHEMATOSUS AS AN IMITATOR OF VARIOUS FORMS OF DERMATITIS

The author said that lupus erythematosus as an imitator of various forms of simple dermatitis was a formidable rival of syphilis itself It was to this aspect of the disease that he desired to direct attention by relating some cases and showing drawings which illustrated the points he wished to place before the Association

The first drawing was an instance of a lupus imitating erythema tuberculatum The patient was 27 years of age The lesions commenced on the right cheek There was only one spot for the first two years, then others formed on the side of the nose, and they then became scattered irregularly over the face, but with the exception of a hempseed sized nodule on the left ear, there were none anywhere else The lobes of both ears were atrophied looking, but the patient said there had never been any lesions on them All the lesions were exactly like an erythema tuberculatum, varying from a hempseed to half an inch in diameter, quite smooth except one on the side of the nose, which was scaly They were of a uniform purplish-red except one, which was whiter in the center

Case 2 showed an advanced condition of the disease, which began in a similar form to Case 1

Case 3 was one of lupus erythematosus, like erythema papulatum The patient, aged 42, was a cab driver Two years previously he had some rash on the cheeks which lasted only a month, and it was not until a year ago that the present eruption began on the sides of the cheek, and has gradually extended until it reached its present condition The eruption when seen occupied the whole face below the eyebrows, the orbits themselves and the lower lip escaping, but the chin, except in the center, was affected On the left side it extended above the brow, but below the orbits which was remarkably symmetrical The most recent lesions were on the lower part of the side of the face and below the jaw In these positions they were the form of erythematosus, slightly raised discs from a half to a quarter of an inch in diameter, the most recent were quite smooth and slightly convex, the larger ones were not prominent in the center and but slightly scaly

Case 4 was like diffuse erythema, the patient being a lady 43 years of age The disease had commenced three years previously as a small red spot on the side of the nose and had spread continuously, the whole nose was intensely reddened and slightly scaly, the skin thickened and infiltrated, but the orifices of the sebaceous glands were not patent or plugged

Another disease which lupus erythematosus imitates is psoriasis, and the author reported a case in point A rarer imitation is that of lichen planus, of which the author had seen only two cases

Dr Crocker also reported a case of lupus erythematosus nodulatum He had met with three or four other cases of this, but not with so many distinct foci of disease In two cases there was only a single nodule in each He also remembers a case in which there were even more foci of disease in a patient of the late Dr Tilbury Fox Cavafy also showed a man at the Dermatological Society of London, in 1892, but Dr Crocker was not aware of any other cases having been recorded

(*To be continued*)

New York State Medical Association—Program of the proceedings of the tenth annual meeting, to be held at the Mott Memorial Hall, on Madison Avenue Introductory, Monday, October 9, 1893

Evening Session, 8 o'clock—1 Address of Welcome, by the chairman of the Committee of Arrangements, J G Truax, M D, of New York Co 2 Address by the president 3 Address The medical work of the Association during its first decade, by John Shrady, M D, of New York Co Collation

First Day, Tuesday, October 10—*Morning session, 9 o'clock* Order of business *a* Calling the meeting to order *b* Report of the Committee of Arrangements *c* Address of the president Read at evening session October 9 *d* Annual report of the council *e* Report of special committees *f* Unfinished business *g* New business *A* Annual reports of the presidents of branch associations, in their numerical order, to be read by title *B* Annual report of the president of the New York County Medical Association, to be read by title

4 Address The surgical work of the Association during its first decade, by Stephen Smith, M D , of New York Co

5 ' Report of eight cases of placenta prævia," by Zera J Lusk, M D , of Wyoming Co

6 " Penetrating wound of anterior fossa through orbital plate of frontal bone Recovery," by Zera J Lusk, M D , of Wyoming Co

7 "The treatment of epithelioma and the cancroid ulcers by topical application," by Nelson J North, M D , of Kings Co

8 "Prevention of disease" by James G Porteous, of Dutchess Co

h Announcement by the presiding officer that the Fellows from the different districts shall appoint two members of the nominating committee from each district *i* Appointment by the president of a member at large of the nominating committee *j* Adjournment of the session During this recess of half an hour, the Fellows from the different districts shall meet to appoint the two members of the nominating committee from each district

First Day, Tuesday, October 10 —Afternoon session, 1 o'clock Discussion on lesions of the pleura 9 The discussion will be opened by John Shrady, M D , of New York Co , propounding the following questions

Question 1 What are the factors of pleurisy? Its forms and contributive conditions? What are the pathological changes in a case of progressive pleurisy ending in recovery? 10, by Frank W Ross, M D , of Chemung Co 11, by William McCollom, M D , of Kings Co,

Question 2 What are the points of differential diagnosis in pleurisy and other affections of the chest? 12, by Edward F Brush, M D , of Westchester Co 13, by J Blake White, M D , of New York Co 14, by John G Truax, M D , of New York Co

Question 3 What is the treatment of empyema, with relative value of aspiration, rib resection and free opening with tube drainage? 15, by M K Hogan, M D , of New York Co 16, by Charles A Leale, M D of New York Co

17 "The surgical treatment of pulmonary cavities," by N P Dandridge, M D , of Cincinnati, O

First Day, Tuesday, October 10 —Night session, 7 30 o'clock

18 ' Remarks on fermentative dyspepsia," by Austin Flint, M D , of New York Co

19 " Open treatment of tuberculous disease of the joints," by T M L Chrystie, M D , of New York Co

20 ' Bloodless amputation at the hip joint Report of cases operated on by the author's method," by John A Wyeth, M D , of New York Co

21 " Report of a case of osteotomy of both femora for the relief of deformity following ankylosis of the hip joints," by Reginald H Sayre, M D of New York Co

Second Day, Wednesday, October 11 —Morning session, 9 o'clock Order of business *a* Calling the meeting to order *b* Communications from the council *c* Reports of special committees *d* Unfinished business *e* New business

22 Address The obstetrical and gynecological work of the Association during its first decade, by George Tucker Harrison, M D , of New York Co

23 " Rare forms of gout and rheumatism," by Sir James A Grant, of Ottawa, Canada

24 "Treatment often indicated after trachelorrhaphy," by William H Robb, M D , of Montgomery Co

25 " ℞," by Henry D Didama, of Onondaga Co

26 "Ten years' experience in the treatment of cataract," by Alvin A Hubbell, M D , of Erie Co

27 "The treatment of enteric fever" by Gustavus Eliot, M D , of New Haven, Conn

28 "Voluntary commitment of the insane to asylums," by W D Granger, M D , of Westchester Co

f Adjournment of the session

Second Day, Wednesday, October 11 —Afternoon session, 1 o'clock

29 ' Surgical and pathological memoranda," by Donald McLean, M D , of Detroit, Mich

Discussion on the treatment of appendicitis 30 The discussion will be opened by Frederic S Dennis, M D , of New York Co , propounding the following questions

Question 1 What proportion of cases of appendicitis end in resolution?

Question 2 What class of cases require immediate operation?

Question 3 What class of cases do not require immediate operation? These questions will be answered by 31 R N Cooley, M D , of Oswego Co 32 Donald McLean, M D , of Detroit, Mich 33 W S Tremaine, M D , of Erie Co 34 Joseph D Bryant, M D , of New York Co 35 John W S Gouley, M D , of New York Co

' *Second Day, Wednesday, October 11* —Evening Banquet Fellows of the Association have made arrangements to celebrate this first decimal assembly by a banquet, further notice of which will be given by the Secretary

Third Day, Thursday, October 12 —Morning session, 6 o'clock Order of business *a* Calling the meeting to order *b* Communications from the council *c* Report of the nominating committee, and action upon such report by the Association *d* Report of special committees *e* Unfinished business *f* New business

36 'The male catheter, with some observations upon the proper mode of introduction into the bladder," by Douglas Ayres, M D , of Montgomery Co

37 " Researches on the efficacy of vaccinia after typhoid fever," by William Finder, Jr M D , of Rensselaer Co

38 "Reflections on the need of close observation of disease and upon the value of hygienic therapeutics," by H Ernst Schmid, M D , of Westchester Co

39 Unique case of traumatic tetanus, with generalization recovery," by John G Orton, M D , of Broome Co

40 " A case of puerperal blindness," by Darwin Colvin, M D , of Wayne Co

41 'A plea for the non-operative method of treating dysmenorrhea, pelvic inflammation and pelvic abscess," by T J McGillicuddy, M D , of New York Co

42 " An additional note on nephrotomy and nephrectomy," by E D Ferguson, M D , of Rensselaer Co

43 " Fifty operations for laceration of the cervix uteri," by J B Harvie, M D , of Rensselaer Co

44 " Brief comments on the materia medica, pharmacy and therapeutics of the year ending October 1, 1893," by E H Squibb, M D , of Kings Co

g Adjournment of session

Third Day, Thursday, October 12 —Afternoon Excursion to the island hospitals by invitation of the commissioners of charities and correction Luncheon will be served on board the steamer, which will start at 1 o'clock from the pier at the foot of 26th Street, East River

Papers may be read "—— either entire, by abstract, or by title only, as may be determined by the council ——

" The reading of a paper shall not occupy more than thirty minutes, except by permission of the Association

"No person shall speak more than once, and then not longer than ten minutes, in the discussion of any paper, except by permission of the Association

"No voluntary communication shall exceed fifteen minutes in length, except by permission of the Association ——"

See By-Laws Article X, Sections 7, 8, 9 and 11

25 Nicholas Senn, Chicago, Ill Subject not announced

26 J H Duncan, St Louis, Mo "Lupus"

27 Ellen H Heise, Canton, Ill Subject not announced

How to become a Member —Extract from the Constitution "Membership in this Society shall be limited to those members of the medical profession who are regular graduates in medicine, and who acknowledge allegiance to the American Medical Association * * * All applications for membership shall be referred to the Committee on Credentials, and shall be accompanied by a fee of two dollars" Extract from the By-Laws 'Every member of this Society shall pay to the Treasurer the sum of one dollar annually before participating in the business of the meeting"

Special Notice —The medical men of Peoria take this opportunity of cordially inviting you to this meeting

Officers —President, Dr W H Martin, Kahoka, Mo, Senior V P, Dr Calvin Snook, Fairfield Iowa, Junior V P, Dr O F Pyle, Memphis, Mo, Treasurer, Dr H S Reese, Wayland, Mo, Secretary, Dr J M Ball, Keokuk Iowa

Committee on Arrangements —Dr W R Allison, Peoria, Dr J F Percy, Galesburg, Dr Frank Parsons Norbury, Jacksonville

The Medical Society of the Missouri Valley met at Council Bluffs, Iowa, on Thursday, Sept 21, 1893, under the presidency of Dr J M Knott of Sioux City The total membership of this Society has reached 365, and it is in a flourishing condition Dr F S Thomas of Council Bluffs, is the secretary

DOMESTIC CORRESPONDENCE

Mr Ernest Hart Replies to Dr Hammond

To the Editor —My respect for and my sympathy with the medical profession in America, and my knowledge of their sentiments, forbid me to regard Dr William A Hammond as their representative in the defense which he puts forward in the columns of the *New York Medical Journal*, Sept. 16, of the practices of publicity hunting, by newspaper interviews, newspaper portraits and of the use of and traffic in secret preparations, etc I have in the course of recent travel received personally from many hundreds of prominent and representative physicians in Milwaukee, Washington, Boston, Philadelphia, Chicago, Cincinnati, Detroit, and from all parts of the United States, their cordial congratulations on the tone and substance of the addresses which I had the honor to deliver at Milwaukee and Washington I have been assured on all hands of the entire sympathy of the great body of the profession in the views therein laid down and discussed I should have been surprised, however, and perhaps disappointed if they had not elicited some expression of pain and anger from certain quarters "Let the galled jade wince, the withers" of the great American medical profession are, I am assured, "unwrung" Your correspondent, in an access of ethical agnosticism, assumes that the enumeration of ethical data as to medical conduct was, or could be, a reproval direct or implied to the medical profession of America That is an unmerited insult which he addresses to his profession, and indicates a view which I apprehend to be special to himself. Let him enjoy the practices which he defends, I do not think he is likely to find much support or sympathy in them from medical men in good standing His account of the position of the medical men in Great Britain is a parody undeserving of serious notice So, as to myself, whom he favors with some personal abuse, I have been avowedly the scientific adviser to, but it is untrue that I have ever held any of the stock of, the Apollinaris Water Company As to his other trivialities, I was the guest of the Pan-American Medical Congress, and on entering its headquarters I registered in ceremonious form

I have no desire to be honored amongst "the Pan-Anglicans,"the "Fat Men of America," and the other objects of lay interest, with whom Dr Hammond puts medical men on a par, and I do not agree with him that medical men should desire to share with them the honor of newspaper notoriety I do not believe any details of my medical career have ever appeared in any lay paper

I suggest that it might be desirable for Dr Hammond to rely less upon his imagination for his facts, and not to assume to speak for a profession from which he has no sort of mandate, and which would, I am well assured, repudiate, if consulted, both his advocacy and his methods of action and of expression

I am assured that he utterly misrepresents that profession, both in his statement of principles which he ascribes to it, and in his abuse of myself I am, sir,

Yours faithfully, Ernest Hart

MISCELLANY

The Chemical Laboratory of the U S Department of Agriculture of the World's Columbian Exposition —Of interest to medical science is the work and exhibit of the chemical division of the National Department of Agriculture in the Government Building at Jackson Park

This exhibit occupies a liberal floor space in the northeast corner of the Government Building, and is designed to illustrate the chemical work of the department in its various aspects The appliances for investigating sugar producing plants are perhaps the most complete of any in the world Full illustrations are given of the analyses of sugar cane sorghum and sugar beets Large numbers of beets are daily reaching the laboratory from different parts of the country and are at once analyzed This part of the exhibit has also been put to good use by the board of awards, several hundred samples of sugars and syrups having been examined for the agricultural jury

A most interesting exhibit shows how the Darwinian law of natural variation has been utilized in the improvement of a sugar producing plant In 1888 experiments were commenced by the department on this line In that year in a plot of sorghum growing in Kansas and submitted to systematic examination, there was found one plant with a phenomenal content of sugar The seeds of this plant were propagated carefully and the progeny again examined None of the progeny reached the degree of perfection of the parent, but many plants were produced showing a content of sugar above the average The best of these was selected for further planting, and this process has been continued up to the present time From this one parent-head, as a result of these continued selections, a variety of sorghum cane has now been fully established having a sugar making value equal to the best sugar cane of Louisiana Last year nearly five hundred selections were made from canes which had an average content of nearly 20 per cent sugar Illustrations are also given of the same line of work with sugar beets

Of most interest to the medical profession, however, are the exhibit and work relating to the adulteration of foods Pure food is an essential to health and every physician is deeply interested in securing to the public, immunity from fraud in this direction, of both a financial and hygienic nature The thesis which is proposed by the exhibit is that all foods exposed for sale should be what their names imply The exhibit shows how far our American food products fail to meet the fundamental conditions of this proposition Honey purchased in the open market is shown to have been made quite independent of the mediation of bees, or at most having only enough pure honey to give the required flavor Coffee beans are exhibited which have been molded from a mixture of meal and molasses Canned goods kept beautifully green by copper make an important addition to this display of the ingenuity of man, unrestricted by any regard for health

The results of the work in this line of investigation do not condemn the use of copper in greening peas, but emphasize the justice of the demand that artificially greened goods should carry a label announcing that fact and stating the character and amount of the added greening material The same remark may be applied to the data obtained by the work of the chemical division in regard to the use of antiseptics in the preservation of food The occurrence of salicylic, sulphurous, benzoic and boric acids is shown to be of wide extent, and attention is called to the fact that the medical fraternity and the people should be informed regarding the use of these preservatives If, then, the patient and his doctor prefer to use such foods, it is a question for them alone, the public has at least done its duty in relation to the matter

There is by no means unanimity of opinion among hygienists in regard to the effect on the human system of continued small portions of salicylic acid, copper, etc, as they occur in the food In fact, opinions on such subjects are of little value unless based on actual experiment At least one thing, however, is certain, viz, that no harm is done in letting the consumer know what he is eating

Every day a large number of chemists may be found busily studying some of these problems relating to foods, and physicians might spend a profitable hour in examining the character of the work

Distilled liquors, wines and beers are also analyzed for the jury of awards, and the final distribution of medals will rest largely on the results of these investigations

One of the very interesting facts of the work is found in the study of the olive oils which are on exhibition It is claimed by the producers of olive oil in California, that they have a powerful competitor in the cotton oil of our Southern States Much of this oil, it is asserted, finds its way to France, Italy and Spain and returns to this country under the guise of pure olive oil The examinations which have been made so far do not afford much comfort to the promoters of that rumor Even were it true, it is not at all likely that foreign exhibitors would place any such adulterated oil in competition There is no manner of doubt of the fact that a large proportion of the salad oil purchased in this country has had its origin in Mississippi and Texas, but such oils are not found to any great extent in Jackson Park masquerading as products of the olive

An important part of the work now in progress in the chemical laboratory consists in the analysis of cereals for the agricultural jury All those cereals—nearly 1,000 in number which have been adjudged worthy of competition by the jury have been sent to the laboratory for examination The weight per unit volume is first determined, whence the weight per bushel is calculated Next, the sample is ground until it all passes a very fine sieve After the removal by means of a magnet, of any iron dust which may have been mixed with the flour through abrasion of the steel mill, the nutrient value of the sample is determined by analysis The moisture, ash, oil, fiber, and albuminoids are determined by direct analysis and the starch by difference On the data thus obtained the food value is calculated For this purpose the percentage of moisture, ash, and fiber is deducted and the nutrient value calculated on the residue the relative values of the starch, oil and albuminoids being as 1 2,5 2 5 respectively On these data and the report of the experts on the commercial value of the samples the awards are made Space does not permit of a more extended notice of the work of this laboratory in food products Above have been mentioned only some of the more important of the investigations But in addition to these, nearly all the food products on exhibition in the Agricultural Building have been subjected to some kind of a chemic examination It is doubtful whether any other work, not strictly of a medical nature, which is carried on at Jackson Park has a more intimate connection with public health and State hygiene than that of the chemic laboratory

The work is under the direction of Dr H W Wiley, chief chemist of the Department of Agriculture of Washington Dr Wiley is himself a graduate of medicine, and while not sacrificing the promotion of agriculture in any way his medical training may be allowed some credit for the direction which the investigation in food products has taken

---

Fair Emergency Hospital Work —Cases Cared for by Exposition Doctors and Nurses Since May 1 —While it is one of the most important institutions connected with the Fair little has ever been said about the work of the Emergency Hospital Under direction of Dr John E Owens the department devoted to caring for sick and injured people from the start has performed its duties most admirably The staff of assistant surgeons is composed of Drs W H Allport, N R Zeager, S C Plummer, and E J Edgerly, with J L Hillsmantel and W C Roughly as resident physicians, W H Gentles, Superintendent of Ambulances, and Miss M R Brown of St Luke's Hospital, head nurse She has at all times a corps of ten trained nurses under her command They are changed every month so as to give others an opportunity to see the Fair These nurses are selected from the best hospitals of New York, Pennsylvania, Massachusetts, Baltimore, Boston, Washington, Chicago, Philadelphia, Toronto, and other large cities Up to Sept 16th 13,765 patients had been treated Out of this number there were twenty deaths, three of them victims of the Cold-Storage fire The record of cases by months is as follows

May	2,621
June	2,966
July	3,292
August	3,169
September (16 days)	1,717
Total	13,765

The great number of cases in May is due to the fact that a great many workmen were injured in various ways The great majority of patients have, so the physicians say, been victims of indigestion, superinduced by irregular eating and change of diet On hot days prostrations were quite numerous July 4, with 170 cases, was the biggest day, and Sept 14, last Thursday, Ohio day, furnished 151 ambulance calls In May were 315, in June 406, in July 581, and in August 564

Increase of Alcoholism in Europe —According to the *Lancet*, June 24, the multiplication of deeds of violence among the Latin peoples of Europe, can be distinctly traced to use of stronger drinks In Southern and Central Europe the human subject is even more susceptible than the dwellers to the north, to the evil influences of alcoholic intoxicants Even the nationalities dwelling along the Mediterranean have, from this cause, during the last decade, raised the crimes of bloodshed to a figure quite appalling

Opening of the Chicago Medical Colleges —The Rush Medical College and the Chicago Medical College respectively held their opening exercises on Tuesday, Sept 26 The introductory lecture was given by Dr Norman Bridge at Rush Medical College, and at the Chicago Medical College by Prof N S Davis

Editorial Change —Dr F S Parsons has been appointed editor of the Philadelphia *Times and Register*, to succeed Dr A F Waugh Dr Parsons has been for many years a member of the American Medical Association and at the last meeting was secretary of the Section on Diseases of Children

Coroner of New Orleans —Dr G B Lawrason has been appointed coroner of New Orleans Parish by Governor Foster, to fill the vacancy caused by the death of Dr Seeman

There has been too much microbe hunting in Hamburg and too little attention paid to general sanitation

THE PUBLIC SERVICES

Army Changes Official list of changes in the stations and duties of officers serving in the Medical Department U S Army, from September 16, 1893, to September 22 1893

Capt Louis Brechemin, Asst Surgeon, is granted twenty three days' leave to take effect about September 17, 1893

Major Henry McElderry, Surgeon U S A is granted leave of absence for one month to take effect about October 1 1893

Capt Curtis E Price, Asst Surgeon, relieved from duty at Ft Wadsworth, N Y, and ordered to report to the commanding officer, Ft Porter N Y, for temporary duty at that post

Capt Wm C Shannon Asst Surgeon is relieved from duty in the office of the Surgeon General of the Army and as assistant to the attending surgeon, Washington, and will proceed to New York City, and report in person to the commanding general, Dept of the East for duty as attending surgeon and examiner of recruits in that city, relieving Capt Guy L Edie, Asst Surgeon

Capt H S T Harris Asst Surgeon U S A is relieved from duty at Ft Keogh Mont and assigned to duty at Ft Preble, Me

Capt M W Wood, Asst Surgeon U S A is relieved from duty at Ft Preble Me, and assigned to duty in Boston, Mass, as attending surgeon and examiner of recruits

Capt Francis J Ives Asst Surgeon ordered to proceed from Ft Sheridan Ill to Chicago, Ill, and report in person to Capt Louis A La Garde Asst Surgeon in charge of the medical section of the War Department exhibit, World s Columbian Exposition for temporary duty

Capt Guy L Edie, Asst Surgeon upon being relieved from duty in New York City by Capt William C Shannon Asst Surgeon, will proceed *to Washington, D C, and report in person to the attending surgeon* for duty in his office

Capt Wm G Spencer Asst Surgeon is granted six months' extension to sick leave of absence granted in S O 108, A G O, May 13, 1893

The Commission of the Surgeon General of the Navy —From one of the military service papers we learn that a fine specimen of the printer's art has just been turned out by the Government Printing Office, being the commission of Surgeon General J R Tryon, U S N. The commission is printed on vellum and is a beautiful piece of work In forwarding commissions to bureau officers care is generally taken that the document is neither folded or rolled, so that the "sheepskin" can be framed without showing wrinkles or deformations The commission of the Surgeon General will be signed by the President in a few days

---

Circular

The Treasury Department has issued the following

Unlabeled baggage of steerage passengers, and unlabeled baggage of second cabin passengers from cholera infected ports or places, to be disinfected at the quarantine station for the port of arrival

Treasury Department Washington D C Sept 19, 1893

To quarantine officers of the United States, commissioners of immigration collectors of customs, steamship agents and others —Department circular No 65, May 4 1893, relating to the labeling of baggage and the issue of inspection cards to steerage and cabin passengers, provides that all baggage of steerage passengers destined for the United States shall be labeled at the port of departure, said label to bear the seal or stamp of the consulate or of the medical officer of the United States serving at the foreign port also, that the baggage of cabin passengers from cholera infected ports or places shall be likewise labeled Information has been received that occasionally pieces of baggage arrive without being labeled as above required

It is hereby directed that any piece of baggage, including hand baggage belonging to a steerage passenger not bearing a label as provided for in said circular, shall be disinfected by steam at the quarantine station for the port of arrival also that the baggage of second cabin passengers coming from cholera infected ports or places, not bearing the label as provided for in said circular shall be likewise disinfected by steam at the quarantine station for the port of arrival

In view of the difficulty of accurately inspecting each piece of baggage while on board ship at the quarantine, commissioners of immigration and custom officers are hereby directed to scrutinize the baggage of immigrants when landed at the immigrant station and should any piece of baggage including hand baggage be discovered to be without a label as above required they are directed to return the same to the quarantine of the port where said baggage shall be disinfected by steam and properly labeled with a certificate to that effect, before said baggage shall be allowed to pass into the United States

Charles S Hamlin, *Acting Secretary*

1893 Department No 141 Marine Hospital Service

INSANITY IN CHILDREN

Read in the Section of Neurology and Medical Jurisprudence, at the Forty fourth Annual Meeting of the American Medical Association

BY HARRIET C B ALEXANDER, A B , M D
CHICAGO
FELLOW OF THE CHICAGO ACADEMY OF MEDICINE, FORMERLY ASSISTANT SUPERINTENDENT COOK COUNTY INSANE HOSPITAL

Moreau (de Tours)[1] with equal force and truth, strikes at the grave psychiatric error involved in the denial by pediatrists, of intellectual, emotional and moral affections of physical origin in the child Such disordered mental phenomena were explained as immoralities, as eccentricities, or as the result of defective education and training From the time of the great physician of Cos, instances have been cited reversing these opinions Not, however, until school over-pressure became a burning question was the subject regarded as a topic of general medical interest The psychological state of the normal child even is much misunderstood Meynert,[2] with exceeding fullness and subtlety, thus outlines the evolution of psychological processes in the child

Kussmaul has shrewdly indicated certain perceptions and movements common to the fetus in utero, which feeds itself, as it were, by swallowing amniotic fluid He also indicates that there may be special motives, such as the more stimulating taste of the fluid after occasional depletion into it of the allantois, which induce swallowing Here, then, there are two alternatives, the fetus swallows or it does not swallow Fetal consciousness is already presupposed, which would exist, however, under circumstances that give but little opportunity for perception The newborn infant at once discovers signs by which it distinguishes between one set of perceptions and another One set of perceptions helps it to define the circumference of its own body, another set belongs to the world beyond it However obtuse this perception may be, though the child may at first not be able to discriminate between the various impressions of space still it is certain that the child's perception of its own body circumference is established very early Among other means by which it learns to distinguish between impressions received from its own body and the outer world are these contact of a strange finger with its own skin excites but one tactile sensation, contact between two parts of its own body excites two tactile sensations, one from the touching, the other from the touched part Furthermore, a number of strange auditory sensations strike the ear of a child, but only the sound of its own voice is accompanied with muscular sensations, and so the attendant muscular sensations help the child to discriminate between movements of its own body and any other movement it may see There is no order of movements, which, under the cover of instinct, can be pushed in between conscious and reflex movements The first instinct of a child would be the instinct for food, but the origin of that has been discussed There is absolutely nothing in the sensation of hunger which would acquaint the child with the means of remedying this pain It obtains naught but the concept of pain In the general restlessness it displays and in the convulsions ultimately resulting from anemia there is nothing which could be likened to an instinct for food If the child has not to depend on its own resources but has a nipple put into its mouth then the sensation thus excited starts the reflex mechanism of sucking The child has thus acquired the concept that the sensation of satiation is connected with the act of sucking, and these two sensory memories are associated with the innervation sensation aroused by sucking, and probably by the scent of the mother's breast That a child should suck at every finger may be attributable to a reflex mechanism, but the sucking of the child in dreams proves that the act of sucking has produced images which have been registered in the cortex The factors of this primary abstract ego are not definitely defined The nature of the ego does not depend upon any definite order of memories, but is determined simply by the most firmly fixed memories

As soon as movements of aggression have taught the child to take hold of things it is evidently under the impression that it is living in a world of sweets, it takes everything to the mouth and licks it A later aggressive movement—kissing—like the first sucking movements, is probably based upon the act of bringing an attractive object to the mouth This latter movement is clearly dependent upon a powerful secondary presentation aroused by its impressions, just as the sucking movements during sleep denote secondary presentations excited in the course of dreams Space vision in the child excites movements of aggression which aim at the possession of the thing it sees, but as it lacks the power of locomotion it has no conception of distance These aggressive reflexes of the upper extremities are no more coordinated in space than the movements of the eyes are before the child has learned to see, and through irradiation these movements become general, leading to a tossing of the whole body, to kicking with all fours and to cutting of grimaces These movements though extravagant are not spasmodic, but must be regarded as results of cortical impulses interfered with by cortical irradiation The acoustic nerve also takes part in reflex impulses, the child that hears others speak or perceives other sounds and noises has the desire to bring forth the same sounds and noises As its cortical functions improve, it develops the secondary idea that the sounds which it brings forth are similar to those of ordinary speech Wundt correctly remarks that the speech of animals consists of so-called sensory sounds, and this is true of children before they have acquired the faculty of imitating syllables In all aggressive movements the child over estimates the possibilities of its powers Experience and an improvement of the power of imitation correct these false conclusions As soon as the child has reached that age when all cortical fibers acquire their white substance, purely reflex movements and those due to irradiation diminish in number In the child the expression of emotion may vary much Under the influence of the apnœtic effect of functional hyperemia attendant upon pleasurable emotions, there will be movements of aggression bespeaking the force of the child's own personality, or there will be spasmodic movements of repulsion (due to irradiation) such as screaming and crying All these expression movements, whether due to irradiation or not, dispatch sensations of innervation to the cortex, which sensations are there turned into "special memories" and serve later on as impulses, starting the entire groups of movements which are involved in expression Consequently, these movements of expression result primarily from stimulation of subcortical centers, just as simple forms of reflex movements serve as the foundation upon which, the structure of more complex, conscious movements is raised As soon, however, as these irradiatory impulses, which excite the mechanism of expression, are put under control of an organ of motor coordination, they acquire secondarily a higher value as psychical factors of expression In the child, pleasurable emotions result in general movements of the entire body Even in the adult, who dances for joy or performs other extravagant movements, occurs a repetition of these primitive mimical movements of the child A state of excessive pleasurable emotions may pass into a condition of maniacal excitement as a result of dilatation of the arterial network of the brain, or a state of pleasurable confusion may end in a transitory swoon The doctrine that ideas are inherited and are not the result of perception and association, that movements, even mimical ones, are the result of innate motives and have nothing to do with imitation and early reflexes can hardly be applied to man Not even the upright gait is innate, it is acquired with difficulty only through imitation and cortical coordination

[1] Folie chez les Enfants

[2] 'Psychiatry," Sachs' Translation

Dickson has found insanity in children characterized by subacute maniacal symptoms, garrulity or loquacity, or melancholiac depression associated with homicidal or suicidal tendencies The children are often bright, but irritable and wayward

As Perez has shown, anger appears very early in children In the first two months the child shows by movements of its eyelids and hands strong anger when the attempt is made to bathe it or to take something from it

According to Fenelon, jealousy is much more violent in children than is usually suspected Bourdin claims that all infants are liars He, however, ignores the fact that the weak inhibitions of the child prevent it from distinguishing clearly between the subjective and the objective—between its wishes and facts This condition is essentially one of mental instability and underlies the mental states at the foundation of terror and suspicion As might be expected, cruelty is very frequent in childhood Not from an innate tendency to cruelty *per se* as claimed by La Fontaine and Montaigne, but, because as has been shown by Meynert, the feeble secondary "ego" does not so dominate the primary "ego" as to enable it to recognize the feelings of others In certain cases this secondary "ego" is not developed, because of inherited, congenital or acquired defect or perverted training

Motor explosions, for reasons already pointed out by Meynert, readily occur in children, whence the fact noted by Dr Grace Peckham Murray[3] that neuroses in children tend to be motor rather than sensory, since the reflex arcs of which the motor strands form a part are earliest perfected, so that when a sensory stimulus sets free a nerve energy it is likely to overflow into motor paths Intellectual comprehension of sensation, and consequently of pain is the last to be developed, in consequence, severe nervous shocks which would give rise to exquisite pain in the adult, result in a motor neurosis in the child

Motor neuroses, as already stated, readily pass into the motor expressions of psychical disturbance, and from these psychical disturbances intensified by the feeble power of discriminating between the subjective and objective, result the hallucinations so frequently noted in children

The disturbance of the feeble ego results in the appearance in the mental foreground of the child, of cruelty, mendacity, and other primitive instincts Abulic speech, as Dr J H Kellogg has shown, may occur in the instinctive insanities of childhood from morbid tendencies to commit improprieties of speech (*American Journal of Insanity*, 1892)

The child, therefore, gradually acquires a series of checks on its explosive tendencies and the egotism shown in the over estimate of the possibilities of its powers These elements underlie the mental state of childhood, which, according to Moreau (de Tours)[4] is characterized by an absence of reflection and self-control, by spontaneous and capricious actions, by dominance of immediate sensory impressions and absence of regard for the future, by desire for power and tyrannical use of it In a study of these phenomena, classification becomes a necessity and the following modified from Moreau (de Tours), is an excellent basis for such study, especially if it be remembered that even the "pure neuroses" in childhood are often attended by mental symptoms The classification of the psychoses is based on Spitzka

- Neuroses
  - Convulsions
  - Nervous laughs
  - Nervous coughs
  - Hiccough
  - Stuttering
  - Neuralgias
  - Ecstasy
  - Hysteria
  - Chorea
  - Epilepsy
  - Somnambulism
- Psychic Types
  - Hallucinations
  - Anomalies of character
  - Aberrant sentiments
    - Love
    - Jealousy
    - Anger
  - Imperative conceptions
    - Pure,
    - Attended by impulsive acts
      - Arson
      - Suicide
      - Violence
      - Homicide
      - Alcoholism
      - Theft
      - Rape
      - Non criminal acts
  - Idiocy
  - Imbecility
  - Night terrors
  - *Mania*
  - Acute confusional insanity
  - Melancholia
  - Transitory frenzy
  - Stuporous insanity
  - Katatonia
  - Paranoia
  - Periodical insanity and hebephrenia

The imperfect coordination of the slowly acquired inhibitions is readily upset, whence occur states of uncertainty and resultant terror "Night terrors" were the earliest morbid mental phenomena noticed in children "Pavor nocturnus" described by Hippocrates was worthy the clinical insight of the great physician of Cos The emotion of fear, as Meynert has shown, characterized by greater excitement and attention, is probably the neurosis of a subcortical center (of the medulla) which defies cortical inhibition Movements of flight may therefore be started by allied associations in the absence of real danger, and even against the will this underlies the conditions found in "night terrors" and explains the running which so frequently precedes epilepsy in children, the so called epilepsia cursiva The motor elements in childhood's neuroses are therefore not so pure as they at first seem The sensory inhibitions which enabled the child to determine its own movements from those of others remain dormant, it is true, to spring to the surface in constitutional disorder, not as inhibitions but as sensory accessories

Among the earliest manifestations of morbid mental activity in children are hallucinations which depend on already registered perceptions Hallucinations of all the senses may occur, but those of sight are most frequent, next, those of hearing, while taste and smell but exceptionally occur These hallucinations are readily excited by simple causes, like indigestion, and are present in night terrors which are an intensification of the hypnogogic hallucinations that occur in many adults on awakening In many instances even moral agencies produce sudden explosions of mental disorder

The inherited tendencies of childhood predispose to these attacks As Clouston has shown, neuroses and psychoses not requiring hospital treatment are by no means uncommon in the "too sensitive" child with hereditary taint Children of this class take "crying fits" and miserable periods on slight or no provocation These tendencies are aggravated by the results produced by the maternal mental state The silly threats of mothers often cause such brief attacks He has seen a boy of five become intensely depressed, cry and moan for hours because of the "hell" which its mother described as the portion of bad boys who tore their pinafores, sinned against God, and disobeyed their mammas

In predisposed children, subjective frights and unpleasant dreams originate persistent anxieties and hebetude In such children, precocity, over-sensitiveness, unhealthy strictness in morals and religion for a child, a too vivid imagination, want of courage, thinness and craving for animal food are common characteristics These children are over-sensitive, over-imaginative, and too fearful to be physiologically truthful, and tend, under fostering, to be unhealthfully religious, precociously intellectual, sensuously artistic, and hyperesthetically conscientious He points out that what he calls "delirium of young children" is relatively frequent "In most cases it is a pure delirium, without consciousness, attention, or memory, but in some instances there are frightful hallucinations In others, an excited melancholia of short duration " "The same children who suffer from delirium at low temperature are those subject to 'night terrors' chorea, epilepsy, hysteria, and even adolescent insanity (hebephrenia) at later ages "

Krafft-Ebing state that "night terrors" are peculiarly frequent in neuropathic children

Dreams, somnambulism, and night terrors, according to C P Putnam,[5] find their explanation in a loss of the higher and exaltation of some of the lower cerebral functions The conscious life of the individual is in the realm of the higher functions, which exercise an inhibitory influence on the low

Steiner[6] believes that of the immediate causes of "night terrors" and the resultant states, the most important are a bad mental training, ghost description ere retiring, and going to bed in the dark, all of which are calculated to stimulate the lively intelligence of children already timid and excitable

In regard to the frequency etiology and types of the various psychoses and neuroses much variance of opinion exists The frequency with which chorea occurred among degenerates led to an expression of opinion that all choreic children were morally imbecile The question will, therefore, naturally arise as to the existence of degeneracy in the family of a given child "Degeneracy," according to Morel[7] the apostle of the doctrine, "is the result of a morbid influence, physical or moral An essential characteristic of degeneracy is hereditary transmission, but of a grave type and more far reaching in consequence than ordinary heredity " This factor plays an exceedingly important rôle in the disorders of childhood In infancy, are born errors and prejudices almost never uprooted, above all credulity Although impressions are mobile, still something remains therefrom for the future The child is dominated by the most pressing appetite and instability resembling that of the ape (as described by Milne-Edwards), or the hysteric is in the main uppermost in childhood Cabanis has shown that there is no moral distinction between the psychic life of the sexes in childhood at the outset Upon the power of acquiring checks, turns the after life of the child and this power is lessened by the cortical deficiencies due to degeneracy which also creates the predispositions to which reference has already been made Under "insane diathesis" or "insane temperament" has been placed a congenital predisposition most graphically portrayed by Dr C F Folsom [8]

> "It is closely allied to insanity and the neuroses, and at the critical periods of life is exceedingly apt to develop into one of them It is congenital or due to early interference with normal brain development It shows itself in childhood and infancy by irregularity or disturbed sleep, irritability, apprehension, strange ideas, great sensitiveness to external impressions, high temperature, delirium or convulsions from slight causes, disagreeable dreams and visions, romancing, intense feeling, periodic headache, muscular twitching, capricious appetite and great intolerance of stimulants and narcotics At puberty developmental anomalies are often observed in girls and not seldom perverted sexual instincts in both sexes During adolescence there are often excessive shyness or bravado, always introspection and self consciousness and sometimes abeyance or absence of the sexual instinct which, however, is frequently of extraordinary intensity The imitative and imaginative faculties may be quick The affections or emotions are strong Vehement dislikes are formed and intense personal attachments result in extraordinary friendships which not seldom swing around suddenly into bitter enmity or indifference The passions are unduly a force in the character which is said to lack will-power The individual's higher brain centers are not well inhibited and he dashes about like a ship without a rudder,

fairly well if the winds be fair and the seas calm, but dependent on the elements for the character and time of the final wreck Invention, poetry, music, artistic taste, philanthropy, intensity and originality are sometimes of a high order among these persons but desultory, half finished work and shiftlessness are much more common With many of them concentrated, sustained effort is impossible and attempts to keep them to it impossible Their common sense, perception of the relations of life, executive or business faculty and judgment are seldom well developed The memory is now and then phenomenal They are apt to be self conscious, egotistic, suspicious, and morbidly conscientious They easily become victims of insomnia, neurasthenic, hypochondriacal, neurotic, hysterical or insane, and they offend against the proprieties of life or commit crimes with less cause or provocation than other persons

At the same time that many of them are among the most gifted and attractive people in their community, the majority are otherwise and possess an uncommon capacity for making fools of themselves, being a nuisance to their friends and of little use to the world If such children could be placed in the hands of judicious and experienced physicians much better results could be obtained and the downward tendency might be stopped"

Among those beings termed by him the "neurotics" Dr E S Talbot[9] has found anomalies of the jaws and teeth exceedingly frequent Such stigmata of degeneracy were to be expected The "lithemic" child, of pediatrists, belongs but too often to this class, the lithemia being an expression of degeneracy Here, also, very often belong the infant prodigies like the two-year-old negro calculator described by Dr S V Clevenger,[10] and the host cited by Moreau de Tours Such precocity is a mental stigmata and, like early puberty appears so often among the degenerate as to give rise to the proverb, "a wit often is a fool at thirty" Shelley is an excellent instance of this 'insane temperament"

He was somnambulistic from his sixth year[11] From "very early childhood" he was an imaginative and restless child Trifles unnoticed by most children, seem to have made keen and permanent impressions upon him—the sound of wind, the leafy whisper of trees, running waters The imaginative faculties came so early into play that the unconscious desire to create, resulted in the invention of weird tales of legendary creatures, tales sometimes based on remote fact, in attempted delusion of neighbors and in the experience of more or less positive hallucinations His memory surprised many of his friends He delighted in "weird and somber tales of the supernatural and horrible" He was extremely desultory and careless in all his habits His room was a chaos of scientific instruments, chemicals and books "From thinking the best of friends and acquaintances he could of a sudden, and with insufficient cause, pass over to the other side and think the worst" Like all neuropathics he was easily hypnotized He was a great hypochondriac On one occasion, meeting a woman with large legs he was seized by the notion that she had elephantiasis and had infected him Medical examination demonstrated the falsity of this notion but it persisted for several days "One evening he actually arrested the dancing of a line of pretty girls proceeding to examine their arms and necks with such woebegone gravity that they were terrified and their angry partners silent" He suffered frequently from the topoalgias so frequent in neurasthenics and hypochondriacs His flagrant violations of social conventionalities were notorious Many of these, however, had, as Symonds has shown, logical bases from the Shelleyan standpoint of reaction against social tyranny not unnatural to a mind early subjected to the brutal "fagging" of English schoolboys and brutality of schoolmasters who found a "voluptuous ecstasy" in flogging boys ere entering on the "feast of reason, flow of soul" of a banquet whereat the flogger was the "genial, humorous" host Shelley however, violated his own code in a most capricious manner An avowed atheist, he took the sacrament in a blatantly audacious manner for interested reasons He reverted to fetichism and argued for the existence of ghosts He denounced legal marriage, but, married Harriet twice, once by the simple Scotch common law and once by the English church rite The constant nagging of his intriguant "sister in law" which drove Harriet into 'nerves" and him into home hatred, led to the estrangement of wife and husband The hysteric insensibility of the wife to her own children fostered this Shelley's temperament, however, aided this tendency He "took strange caprices, unfounded frights, vain apprehensions and panic terrors, and therefore absented himself from formal and sacred engagements" In a month after the English marriage he deserted Harriet and her unborn child, to elope with Mary Godwin Even Symonds, the most logically psychological of Shelley's analysts, fails to justify this act from Shelleyan principles In Shelley's case hereditary degeneracy existed He normally reacted against school tyranny, hence it alone does not account for the defects and peculiarities of his career

School training, however, may develop very similar states and wreck many a nervous system Such an acquired predisposition is singularly well illustrated in the lives of Margaret Fuller and George Eliot Margaret Fuller says[12]

'My father instructed me himself At the outset he made one great mistake, more common, it is hoped, in the last generation than the warnings of physiologists will permit it to be in the next He thought to gain time by bringing forward the intellect as early as possible Thus I had tasks given me as many and various as the hours would allow, and on subjects beyond my age, with the additional disadvantage of reciting to him in the evening after he returned from his office As he was subject to many interruptions, I was often kept up until very late, and as he was a very severe teacher, both from his habits of thought and his ambition for me, my feelings were kept on the stretch till the recitations were over Thus it frequently happened that I was sent to bed several hours too late, with nerves unnaturally stimulated The consequence was a premature development of the brain that made me an 'infant prodigy,' by day and by night a victim of spectral illusions, nightmare and somnambulism, which at the time prevented the harmonious development of my bodily powers and checked my growth, while later they induced continual headache, weakness and nervous affections of all kinds As these, again, reacted on the brain, giving undue force to every thought and every feeling, there was finally produced a state of being both too active and too intense, which wasted my constitution and will bring me—even although I have learned to understand and regulate my now morbid temperament—to a premature grave No one knew why this child, already kept up so late, was still unwilling to retire My aunts cried, 'Out upon the spoiled child, the most unreasonable child that ever was—if brother could but open his eyes to see it—who was never willing to go to bed' They did not know that, soon as the light was taken away, she seemed to see colossal faces slowly advancing toward her, the eyes dilating and each feature swelling loathsomely as they came, till at last, when they were about to close upon her, she started up with a shriek which drove them away, but only to return when she lay down again They did not know that when at last she went to sleep, it was to dream of horses trampling over her, and to awake once more in fright, or (as she had just read in her Virgil) of being among trees that dripped with blood, while she walked, and walked, and could not get out, while the blood became a pool and plashed over her feet, and rose higher and higher till soon she dreamed it would reach her lips No wonder the child rose and walked in her sleep, moaning, all over the house till once when they heard her and came and waked her, and she told what she had dreamed, her father sharply bid her leave off thinking of such nonsense or she would be crazy, never knowing that he himself was the cause of all these horrors of the night"

To these influences Emerson[13] rightly referred her later demonology, with its curious superstition and imperative conceptions He says

"Her childhood was full of presentiments She was then a somnambulist She was subject to attacks of delirium, and later perceived she had spectral illusion When she was 12 she had a determination of blood to the head 'My parents,' she said, 'were much mortified to see the fineness of my complexion destroyed My own vanity was severely wounded, but I recovered and made up my mind to be a fright and ugly' She was all her lifetime the victim of disease and pain She read and wrote in bed, and believed that she could understand anything better when she was ill Pain acted like a girdle to give tension to her feelings A lady who was with her through an attack of nervous headache which made Margaret totally helpless, assured me that 'Margaret was yet in the finest vein of humor, and kept those who were assisting her in a strange, painful excitement between laughing and crying, by perpetual brilliant sallies There were other peculiarities of habit and power When she turned her head on one side she alleged she had second sight, like St Francis These traits and predispositions made her a willing listener to all the uncertain science of mesmerism and its goblin brood which have been rife of late years' (1849) She had a feeling she ought to have been a man, and said of herself 'A man's ambition with a woman's heart is an evil lot' In some verses which she wrote 'To the Moon' occur these lines

> 'But if I steadfast gaze upon thy face
> A human secret like my own I trace,
> For through the woman s smile looks the male eye

And she found something of true portraiture in a disagreeable novel of Balzac, 'Le Livre Mystique,' in which an equivocal figure exerts alternately a masculine and a feminine influence on the characters of the plot

The same tendencies are demonstrable in George Eliot Strongly skeptical and virile in type as was the intellect of George Eliot, her childhood was marked by phenomena of like causation to those already described in Margaret Fuller Like Margaret Fuller she had a father of ' extraordinary determination of character" Her mother was a "woman with an unusual amount of force" but of "ailing habit" George Eliot during childhood "suffered from a low general state of health and great susceptibility to terror at night," and the liability "to have all her soul become a quivering fear" remained during life She suffered from periodical depression which later gave place to migraine evidently of uric acid type, and often attended with rheumatoid phenomena She was "an awkward girl, reserved and serious far beyond her years, but observant and addicted to the habit of sitting in corners and watching her elders" Fear of the unknown in children, seemingly a reversion to the fear of the unknown of savages, tends like it to produce occult belief This has been pointed out by Emerson in the case of Margaret Fuller Despite the German rationalism of George Eliot, such fear found utterance in her "Beyond the Veil," a mystically occult contrast with her novels and with the Positivism which was her religion The philosophy of George Eliot should theoretically have effaced such mysticism, yet, as a survival of "night terrors," it came to the surface

Dickens teaches a lesson in school training eminently worthy of study when, in discussing the model school in "Hard Times," he says about the teacher

> "Ah! rather overdone Mr Choakumchild! If he had only learned a little less, how infinitely better he might have been taught much more He went to work in the preparatory lessons not unlike Morgiana in the ' Forty Thieves"—looking into all the vessels before him, one after another, to see what they contain Say, Mr Choakumchild, when from thy boiling store thou shalt fill each jar brimfull by-and-by, dost thou think that thou wilt always kill outright the robber Fancy lurking within, or sometimes only maim and distort him?"

The career of the modelly trained moral imbecile, "Gradgrind," is an apt illustration of the results of this system His case is one of the extreme results of school over pressure in which the struggle for marks before maturity more than equals in fierceness and intensity the struggle for good after it In certain respects this school over pressure checks even in well developed minds the transition from the terror of the unknown of childhood into the calmness of maturity Many morbid fears, imperative conceptions and acts, which torture the individual during an otherwise healthy career, unquestionably originate in the earlier periods of life

The treatment of the degenerate offspring of degenerate parents is one of the most serious problems which confront the physician Although the parents may be convinced of the necessity for extreme caution in the rearing of their children, their inhibitions are too weak to carry out the treatment decided upon In complete separation is the only hope of ever accomplishing anything by the training of the weak inhibitions of the degenerate and this course is practically impossible Degenerate mothers are excessively fond of their children after a maudlin fashion, and their egotism causes them to think themselves model mothers I have had such a mother consent to turn over entirely the training of her child to a person recommended by me, and yet at the first attempt of the companion to exercise authority over the child, the mother told the child to do as it pleased These children need a nourishing, stimulating diet, an outdoor life, regular hours and regular employment, in fact, they require the very life which is led by the healthy children of healthy parents, but which they rarely get unless one of the parents happens to be of sound mind and strong will and financially circumstanced to control the surroundings of the children

Dr W S Christopher, in a paper recently read before the Chicago Academy of Medicine,[13] has laid stress on the nutritional influences, active in the production of neuroses underlying psychic states, and these deserve more attention than they have received

Beside hereditary and the other predisposing causes cited already, Dr Welt very correctly has said that the etiological factors in the production of mental disturbances in children are injuries of the head, either during parturition or later, acute cerebral trouble and abnormal development of the brain, fright, masturbation and infectious diseases may act as predisposing elements Among the chief exciting causes are the fevers

Thore has shown that psychoses following acute diseases are of two classes, the first is met with during the development and the duration of the acute process itself, while the second class is found only during convalescence, or at least during an intermission of the disease The etiology, as well as the course and the issue in these two groups—the febrile and asthenic deliria—differ considerably

Kraepelin points out that in pathogeny of the febrile deliria the exciting cause prevails considerably over the predisposition, the causes of the disease are dependent upon somatic disturbances. Hence the monotony of the febrile deliria, the short course, and the nearly always favorable issue with the disappearance of the etiological cause, on the other hand, the predisposition of the individual forms the most important factor in the development of the asthenic form The lowered state of the system, depressed by the preceding fever and infection, exhibits itself more when the circulation is retarded during the decline of the fever, and the brain which may have suffered in its vitality by the preceding rise of temperature, is the first organ that reacts on the inadequate supply of blood, besides, there may be an influence of the infectious elements upon the central nervous system, either by affecting the ganglionic cells, or indirectly through a change of the blood by the microorganisms In the deranged equilibrium of the system even slight irritating influences, afforded by the events of daily life and frequently overlooked, may cause mental disturbances. In their course the asthenic psychoses resemble the mental derangements of spontaneous origin, and usually terminate in full recovery, with convalescence and better nutrition brain morbidity disappears. Dr. Sarah Welt advises that as a matter of prophylaxis, children after acute diseases, especially when in an anemic and poor condition, ought not to be allowed to leave the bed too early, and the action of the heart should be carefully controlled. Threatening spells of weakness ought to be prevented by administration of good nourishment and stimulants. In occurrence of deliria strict control of the patient becomes necessary, bed rest and a generous administration of alcoholics and heart stimulants. Against the irritable state of the brain, sedatives in result-giving doses should be used.

---

[13] Medical Standard, Aug 1893

Dr. Kiernan states that the psychical manifestations of the febrile stage of any disorder are usually an hallucinatory delirium or acute confusional insanity. These may be agreeable in type. With a fall in temperature occur asthenic psychoses, characterized by visual and auditory hallucinations and their consequences. These are due to acute exhaustion of the nerve centers succeeding to considerable thermic oscillations. The mental symptoms of the febrile stage may aggregate temperature oscillations and in turn be aggravated.

Spitzka[14] finds that febrile and other acute disorders sometimes cause serious and incurable insanity usually combined with more or less arrest of development. This result is most apt to follow when some moral cause, such as a shock is superadded. From 10 to 30 per cent. of infantile insanity is attributable to the acute diseases of childhood, the overwhelming majority being sequelæ of the exanthemata (excluding cases followed by simple imbecility). Scarlatina, measles, typhoid and acute articular rheumatism are most to be dreaded in reference to their immediate mental sequelæ. Typhoid is especially deleterious. Nasse classifies the febrile insanities according to their period of development: *a*, coincident with the fever as to time and ranging from delirium to insanity; *b*, developing as an apparent aphasia and dementia. Spitzka found but 7 per cent. of his cases attributable to these causes. This low percentage was due to the fact that he did not include fatal cases nor ephemeral deliria, which in children, as Hughes and McBride[15] have shown, replace malarial attacks and which are benign, self limiting and not apt to come under alienistic care, like the more serious and protracted mental complications which may attain pseudo cretinism. Aside from an infrequent hallucinatory delirium, there is a continuation of the specific somatic disorder, so that a true convalescence can not be said to have existed. This is often associated with hyperthermia; *c*, developing during convalescence. These last, Spitzka[16] is of opinion, are different from the other two, are probably more benign and are anemic or adynamic. Spitzka states that sudden changes of temperature uncomplicated by other causes can produce transitory frenzy and acute delirious states. This is equally true of the extremes of temperature. Over exposure to the sun and exposure of the unprotected head of an infant to a hot stove have been declared responsible for the same acute delirious or furious outbreaks that Reich observed in children who, after long exposure to severe cold, suddenly entered a warm room.

Rapid cure of a maniacal delirium after the expulsion of ascarides in several cases proves, in Spitzka's judgment, that a parasitic etiology has been correctly assigned for these cases. These mental disorders are usually of acute type.

The parasites which have their seat low down in the bowel have a less direct relation to mental disturbance when, as in not a few cases, they provoke masturbation by the scratching of the anus they cause, or by wandering into the genital passages. The forms thus produced vary from the precipitation of hebephrenia to a stuporous insanity, or an acute hallucinatory confusional insanity of favorable prognosis.

As to frequency, Dr. Sarah B. Welt[17] remarks that insanity in the first ten years of life, aside from idiocy is very rare. Out of ten thousand inhabitants, Emminghaus found in Germany, between the first and fifth years, 0.18 per cent. insane; between the sixth and tenth years, 0.69 per cent.; and between the eleventh and fifteenth years, 1.46 per cent. insane. Debouttevillle, in France, found among the insane admitted to the asylum in Saint-You from 1827 to 1834, 0.9 per cent. between the fifth and ninth years; 3.5 per cent. between the tenth and fourteenth years; and 20 per cent. between the fifteenth and twentieth years. Turnham found but eight children less than ten years of age among 21,333 insane; idiots, who are far more frequent in number, not being included. The most common mental derangement in childhood is idiocy, be it congenital from insufficient development of the brain, or acquired from previous cerebral disease. Next in frequency is maniacal exaltation, while depression occurs only in late childhood. Insanity in childhood in her opinion occurs more frequently than is evident from the statistics. As no psychosis in childhood shows the entire complex of symptoms as in adults, it is readily understood that the symptoms of a mentally deranged child may often be taken to be bad behavior, and only the result, mental weakness, will be recognized.

The neuroses, properly so-called, are beyond the scope of this article. All of them may be accompanied by psychical symptoms. Hysteria, convulsions, ecstasy and chorea may occur in epidemic form especially during religious revivals. The child crusades were mixtures of these epidemics with psychical ones.

Epilepsy and hysteria in childhood as in adult age present their characteristic mental phenomena. Extreme cruelty, as in the case of the boy fiend, Pomeroy, may long be the only manifestations of the epileptic neurosis. In this age it is well to remember that as Griesinger has shown mental derangement often appears as moderate irritability, persistent or habitual. The child is passionately obstinate, quarrelsome, malignant, and even immorally inclined. Often this mental degradation is dubbed simple wickedness. It may occur as a simple, logical perversion with aimless, errabund tendencies, intellectual and emotional perversion with excitement. These children can not keep still a moment. They talk incessantly and incoherently, and are very inattentive. There are sometimes longer or shorter attacks of mania In children of from 3 to 4 years attacks of crying, of wild refractoriness, of striking and morbid destructiveness occur These may alternate with epilepsy, chorea, stupor, ecstatic cataleptoid states (simulating katatonia) The child may remain for hours or days as if quite absorbed, with open eyes, fixed countenance and peculiar position, sometimes breaking out suddenly into loud cries Hypochondriacal states develop in children of parents morbidly anxious about the health of their offspring

According to Shaw[18], in children the ideas are simple, few and disconnected They are therefore incoherent because of an absence of organic associations between the residua The morbid phenomena are not systematized as in the adult, and the result is (according to Maudsley[19]) delirium rather than mania The morbid idea in the child's mind having little range of action acts downwards (Maudsley) on the sensory ganglia, causing hallucinations or giving rise to morbid impulses These impulses constitute impulsive insanity, called by Maudsley, monomania, and by Morselli, paranoia rudimentaria impulsiva

Under the head of monomania Maudsley places the epidemics of morbid ideas which have from time to time in the history of the world affected children The ruling instinct in a child of 3 or 4 is self-gratification, involved in which is a tendency to destroy what it dislikes Its insanity is manifested by perverse and unreasonable appropriations of whatever it sees, and by extreme destructiveness It suffers from the instinctive variety of moral insanity Maudsley describes a cataleptoid type of insanity resembling katatonia

The instability of childhood is shown in the presence of garrulity, melancholiac depression or excitement maniacal exaltation of the pleasant deliria type and instinctive tendencies Exaltation and delirium is usually contemporaneous with the beginning and acme of febrile attacks, while depression usually follows the disease The temperature at which delirium begins in a child is, as Clouston has shown, a good index of its brain constitution and temperament The temperature at which delirium sets in is lower in the sensitive Such children, independently of temperature, are subject to gusts of unreasonable elevation during which they are quite beside themselves, rushing about wildly, shouting, fighting, not really knowing what they are about, this coming on at intervals like the attacks of disease

Scherpf[20] finds that mania of sudden inception and furibund character is the most frequent acute type Melancholia often originates in hallucinations and has a tendency to hypochondriacal phases Katatonia may occur Impulsive monomania, paranoia, periodical insanity, and moral insanity are more frequent than the acute psychoses

In W A Hammond's[21] experience the most frequent type of insanity in children is mania, but insanity in children may occur as an affection mainly of the emotions or as characterized by blind and unreasoning impulses to deceit or violence Fixed delusions are not a prominent feature, but there are perverted feelings, indecency, destructiveness, malignancy toward relatives and hallucinations

Kiernan[22] agrees substantially with Clouston and Griesinger, but has noticed that hallucinatory types are relatively frequent

Hecker, Kerlin and Kohler find hereditary types of insanity in children marked by disagreeable variable temper, irritability, lack of self-control, morbid egotism, and often one-sided talent ideas of persecution at times, with impulsive and immoral tendencies

Kirchoff[23] finds that children whose ancestors have suffered from psychoses or neuroses, not alone become delirious from slight causes, such as digestive disturbances, slight fever, teething, etc , but are apt to be depressed for a long time after the ordinary disagreeable events of daily life Mental work at school rapidly exhausts them Fright and punishment excite them to a dangerous degree

According to Moreau de Tours, circular and periodical insanity in childhood resembles in all essential particulars the same psychosis in the adult

Pottier[24] insists that persecutional delusional paranoiac presents special characters in childhood They are wild, unsociable, inclined to solitude and isolation, somber and taciturn, defiant and suspicious, living apart from their comrades, regarding these last as scoffers, and already interpreting to their disadvantage the most insignificant event Such a delusional state may of course have the usual forensic results

Morbid jealousy may present itself at an early age and exercise a decidedly deleterious influence on the heart of the child Love, according to Descuret, explains the passionate attachment often displayed by little girls for dolls In the degenerate, romantic love may occur early Byron at the age of 8 was passionately in love with Mary Duff, a little girl of 10 The news of her marriage eight years later caused convulsive attacks Alfieri and Dante were similarly in love at 9 years Such early love must be regarded as morbid and an expression of degeneracy like precocity and early puberty In the cases reported, other evidences of degeneracy existed Like all precocity it needs restraint, not assistance Pathological anger is exceedingly frequent in childhood Imperative conceptions of all types occur Hughes[25] has observed pyrophobia in a boy of 6, who doused all fire with water Agorophobia, mysophobia, clitrophobia, etc also are relatively frequent

The discussion of the "imperative acts" following imperative conceptions involves many mixed states closely bordering on delusional conditions, from childhood's instability with regard to the difference between the subjective and the objective

With the increasing social tendency to expose children to financial and other mental stress at the critical period antecedent to puberty, suicides, insanity and criminality among children must, in the nature of things, increase In evidence of this, Moreau de Tours gives the following table

Years	15	14	13	12	11	10	9	8	7	Total
1861-65—	63	29	28	11	6	3	0	1	0	141
1866-70—	73	46	25	7	9	3	2	0	1	166
1871-75—	67	42	22	21	11	5	3	3	1	175
	203	117	75	39	26	11	5	4	2	482

In the last ten years forty-two boys and fifteen girls attempted suicide in Russia In the fourteen months ending December, 1891, 62 children committed suicide in Berlin, Germany The youngest had not reached the age of seven The percentage there is higher for the same reason which will increase it here, the increase of school over pressure The exciting cause of the suicide is usually a trivial one One boy killed himself to get rid of "so much dressing and undressing" No less than five attempts at suicide were made during 1887, by children under 14 years of age, resident in a Philadelphia district less than a mile square In three cases the attempts were successful In three of the five cases the moral epidemic nature of suicide was shown in the fact that one suicide was an exciting cause of two suicides and one attempt In all five cases, the approach of puberty had produced its usual emotional disturbance The immediate causes were, as in most child suicides, trivial Hanging was the favorite method, although one girl (who seems to have formed the melancholiac delusion that she had hanged one playmate who committed suicide) took laudanum She recovered from the poisoning and the melancholia St Louis has recently had a very similar epidemic Griesinger states that 6 10 per cent of the suicides in England are of children under 10 years Death does not inspire children with the same fear it does the majority of adults, and the weak ego is easily overcome by the dominant idea of suicide

In dealing with the question of homicide it should be remembered, as Clifford Allbret[26] points out, that in children homicide is, as a rule, an unreflective act The act is in all probability imitative as a rule The child has heard of killing and of death but has no clear perception by reflection of their meaning Homicide by negro children is growing far from rare In two instances in 1892 two ten-year-old negro boys killed a baby brother to get rid of the trouble of minding it Moral imbecility may crop out here and in cruelty to animals Moreau de Tours[27] cites a case in which a four-year-old boy chopped at the face of a ten-months-old nursling Esquirol has observed a prematurely nubile girl of 8 years who had a fixed tendency to kill her stepmother Legrand du Saulle reports the case of a five-year-old boy addicted to masturbation from his third year who had long been noticed by his nurse to be wicked and vicious, who loved to torment younger children He liked to see chickens killed, ordinarily stupid, his intelligence was shown only in mischief Having noticed nosebleed follow the fall of his baby brother he felt an intense desire to see blood flow Profiting by the absence of the nurse he flung the baby down from a table Epistaxis resulted and he rubbed his hands gleefully in blood With complete indifference he answered in reply to all questions that the nosebleed amused him and he would repeat the deed This was also excellently illustrated in one of my cases

> The eight-year-old daughter of a hystero epileptic presented many of the symptoms of degeneracy Intensely cruel, she took delight in torturing those of a weaker nature than herself She was constantly calling the attention of a melancholiac to the screen in her window She knew how to induce the hysterical attacks of her mother and delighted in seeing the attacks although afraid of her mother at that time She delighted in the sight of blood She was a somnambulist Imperative conceptions had been demonstrably present for more than a year Like so many of these degenerates she had an intense appetite for meat

The crimes of Pomeroy, the "boy fiend" of Massachusetts who killed and tortured several small children, were later explained by the appearance of epilepsy, and other cases of children homicides have had like explanations The impulsive type can, of course, occur without epilepsy since the feeble 'ego" of the child is as easily overcome by the homicidal as by the suicidal impulse

Arson results as (Legrand du Saulle remarks) in maniacal, emotional and depressional states in dements, imbeciles and idiots It may also develop in girls ere puberty or as Marc has said, in child servants badly treated by masters and desirous of re-entering under the parental roof Nostalgia results Fire and flames are found to relieve this, whence arson Rape may occur from early precocity in both sexes in the degenerate Thefts often occurs from the same feebleness of the ego which results in homicide and suicide

Dr KIERNAN—There has been too great a tendency in latter days to put heterogeneous psychoses into the Procrustean bed of insanity It not infrequently happens that acute insanity is paranoiacal even when senile Such cases are frequently curable It very often happens that an old gentleman is locked up and regarded as incurable when some treatment would improve his mental condition With regard to the point raised about paretic dementia after sixty years of age, it is well known that there is an enormous number of such cases on record There has been a tendency to call that senile or latent paretic dementia I remember two cases in the same family which elucidates the point that paretic dementia in one generation may occur late and in the next one early In the cases I mention the father had it at 65 years of age and the son at 25 The various types need more than an ordinary line of demarkation and for that reason I am glad to see the subject brought up

With regard to the second paper, of course in a general way many of these mental phenomena in children pass unnoticed There is a great tendency to ignore mental symptoms of ordinary disease and under ordinary circumstances It shows a tendency in a right direction when we begin to study mental disorders resulting from various diseases

Dr FRANK T NORBURY—I was quite pleased to hear the presentation of the subject of mental affection in children I was associated for a time with a feeble minded institution, and having cases coming into the institution from three years up to about twenty, probably the oldest children being about twenty I had some very interesting cases under observation While most of them were cases of marked idiocy, yet there were many of them practically of recurrent insanity The doctor speaks of Dr Kerlin's observations It was in the institution of which he was the superintendent that I served a term and where I met three cases of special interest, all these cases were females and did not come under my special charge The cases of paranoia in childhood, that is those which I would class as paranoia, are probably not frequent but yet there were at that institution several, one of which had very thoroughly systematized delusions of persecution, and another one had some hallucinations at intervals accompanying these delusions I have had quite a number of children presenting epileptic insanity, and we received them in the Illinois institution I had one child 7 years of age committed as insane to the Illinois Central Hospital for the Insane, a boy who presented the symptoms of epileptic insanity quite similar to those of an adult We had several cases in one winter, but we have not at present any under 15 years of age

[26] Tuke s Psychological Dictionary

[27] Homicide par les enfants

Dr Alexander—I do not know whether women doctors have a greater tendency to look into the domestic affairs of their patients, but I want to state a case that I met with recently I had a case of senile insanity on hand and had been warning the members of the family in which there were four married daughters who all had children, the family history being bad, about the care of the children An expert was called into the case and when the daughters questioned him, for I suppose I had aroused their fears, he said "Oh, no, there is no danger, you need not take extreme care of your children It is only the strong-minded who get insane anyway" I have lost my hold on that family I feel that it is a necessity in such cases for the physician when he comes into a family and finds this difficulty to warn the family about the care of the children Yet it is done almost never, where the family really should be warned about the care of their children The children are allowed on the street late at night, allowed tea and coffee that even healthy children should not have, and yet they have never been warned

SOME REMARKS ON INSANITY OF THE AGED

Read in the Section of Neurology and Medical Jurisprudence at the Forty fourth Annual Meeting of the American Medical Association

BY FRANK PARSONS NORBURY, M D
JACKSONVILLE, ILL
Lecturer on Nervous and Mental Diseases Keokuk Medical College, Keokuk, Iowa late Assistant Physician Illinois Central Hospital for the Insane, Jacksonville

The tenure of normal mentality in old age, depends on the sum total of vitality originally deposited and the maintenance of normal equipoise in the brain machinery during the years of active engagements in the affairs of life

The blending of the normal and abnormal mental states renders the psychological study of old age difficult, because what is the normal tenure of one approaches the abnormal change in another, the result is, as Clouston has remarked, "the psychology of old age has yet to be written" To the confusion arising from the differentiation of ordinary functional derangements from organic brain diseases, is due the difficulty of diagnosis and clinical classification, which must be experienced to be appreciated

In a clinical study of 196 cases of insanity, occurring in men over sixty years of age, coming under my care, I have been struck by the heterogeneous symptoms, yet similarity of mental affections, when modified by the influence of senility Senility seems to be more or less a common mold in which the mental disorders of the aged are cast, for the mark of the senile change is on them all It is because of the modifying influence of senility, causing variability in the tenure of normal mentality and confusion in abnormal manifestations of intelligence, that there is such a wide difference in the classification of the insanities of the aged In looking over the reports from some thirty prominent State institutions for the insane, I find it is, more or less, the rule to classify distinctive insanities of the aged as senile dementia While it is true senile dementia is the only characteristic alienation of the mind which in its uncomplicated form conforms more to a distinctive type than any other one form of insanity at any age, yet we must not forget that we have other types in the aged as much entitled to consideration, both pathologically and symptomatically, as senile dementia Indeed, all things considered, it seems to me that chronic cerebral atrophy, so often classed as senile dementia, is the most prominent type of senile insanity encountered in institution practice. It is deserving of consideration because it is seldom, if ever, given in hospital reports as a form of senile insanity, having a distinct pathology and recognized symptoms Its pathological difference from senile dementia lies in the nerve cells undergoing, primarily, a *parenchymatous* degeneration, while in the senile dementia there is to be found *infiltration* of the peculiar spider cells of which Lewis has spoken. It is worthy of mention just here, that to Lewis we owe much of the advance made in the pathology of insanity He says, regarding senile dementia and chronic cerebral atrophy, "that we are dealing with two obviously distinct affections of the nervous system

"In senile form we find the results of a general decline in the vital activities, the functions of nutrition, circulation and the respiratory activities diminished The blood is impaired in quality, diminished in quantity, and sluggish in its flow, and when we turn to the verdict of morbid anatomy the blood vessels exhibit diseased tunics, narrowing of their lumen tortuosity with attendant impairment of their resilience accompanying atheroma,—the tissue-elements universally, and the brain cells in particular, presenting fatty changes in their constituents, all indications of a senile retrogressive process

"Chronic cerebral atrophy presents a notable vascular change, but of a very different nature—a compensatory hypertrophy of the muscular tunic of the small vessels, especially emphasized in the cerebral arterioles, and very frequently associated with advanced atheroma of the large basal blood vessels. This hypertrophic condition is found in varying degrees in the kidneys, imperfect renal function being manifested in nearly all of these instances of chronic brain atrophy"

Other distinctive points in pathology are mentioned by Lewis, the pulse being especially important "The senile pulse presents a tortuous artery, unduly prominent and visibly mobile with each pulsation, giving a sphygmogram of exceedingly low tension, a vertical percussion up-stroke, an almost equally sudden collapse and a frequent diminution of the dicrotic wave varying with the endocardial and aortic conditions" In the pulse of the subject "of chronic cerebral atrophy the hardness is so marked that we have often to employ a pressure of 180 grams and with a large hypertrophied heart the pressure often has to be still further increased"

Lewis regards alcohol as a determinal factor in the production of chronic brain atrophy

We know that chronic cerebral atrophy does not, necessarily, exist in what is ordinarily termed the senile period, for it has been observed before the age of thirty, however, it is most frequently found beyond the age of fifty

The mental symptoms are those of despondency with suicidal tendencies, (a recent admission committed suicide within twenty-four hours after coming to the hospital), maniacal outbreaks are not uncommon, inhibited intellection especially amnesia, is marked, transient monoplegia is frequently noticed Vertigo is distressing in some cases and has led to confusion with Meniere's disease These symptoms are not unlike those encountered in paretic-dementia or cerebral syphilis, but are distinguished from them by other associated symptoms, especially of cardiac and renal origin Vertigo is quite noticeable as before mentioned and is probably due as Hirt says, "to the atheromatous condition of the arterial walls, and the consequent irregularities of the blood supply to the brain substance"

The melancholia of chronic atrophy is, we believe, dependent alone on those circulatory changes All have noticed in attacks of acute melancholia of the aged, where cardiac disease was conspicuous, the dependence of mentality upon the stability and regularity of the heart's action In a study of probably thirty such cases, during the past four years, I have satisfied myself that more than renal disease is necessary for the melancholia of cerebral atrophy, and that the circulatory changes are, primarily, the cause of such mental depression Again, the maniacal outbreaks of chronic cerebral atrophy with their explosiveness, incoherence and destructiveness may be of cardiac origin I have noticed, especially in cases complicated with angina pectoris, that the mania was very severe and distressing The fear of impending death, to be noticed in individuals not insane is, in the insane, transposed into hallucinations and delusions, destined to cause great mental disturbance

In the ordinary senile dementia we meet with destructiveness, filthiness and incoherence, the physical and mental helplessness being but the result of the progress of disease

The decline is gradual, the slowness of the atrophic process producing mental symptoms is, at first, regarded as but the natural result of old age, the amnesia, the sudden changes in moods and emotions, and the appearance of delusions being the evolution of distinct senile dementia

The minor details are familiar to you all, and cause you more or less anxiety in their treatment, especially at their homes It is the persistent wakefulness at night of such cases and their tendency to wander away from home, that ultimately leads their friends to have them committed to the hospital Here the career of helplessness goes on until death sooner or later closes the scene In brief, I have presented the characteristics of these two *distinct* mental diseases, having *distinct* symptoms worthy of more study from alienists, especially in their pathological differentiation, which is too much ignored

Another organic disease of the brain, however not frequent, but still it does occur after sixty years of age, is paretic dementia Steadman says that it rarely occurs after fifty, but I have, in the 196 cases of insanity occurring in men over sixty, found seven marked cases Mickle has observed that "owing to the brain strain and exhaustion of the over pressure and blood deprivation in modern life, general paralysis tends to occur at an earlier age than formerly" I may therefore look upon this series of cases as of rare occurrence I rather believe in the agricultural communities, from which most of my patients came, the longevity of such people may be considered as a factor in the cases I have observed Nothing out of the ordinary was noticed in the cases, except in the postmortem examination of one, the very thin skull was interesting, for it is usual, as Wood says, to find hyperostosis and exostosis on the skull This skull was so thin that objects could readily be distinguished through it

Syphilitic disease of the brain was observed in five cases, one made a good recovery, three died and one is still under observation The diagnosis of intracranial syphilis in the aged is difficult, but the symptoms, as outlined by Gray, have materially assisted me in making what I believe to be a correct diagnosis in the five cases above mentioned, the mental symptoms of course confirming my belief The suspicions and hallucinations being especially marked

General paralysis may occur beyond sixty years of age

Syphilitic insanity should not be confused with senile dementia, and the treatment of syphilitic insanity must be vigorously pushed in the aged to avoid chronicity

In conclusion, gentlemen, I would say that the differentiation of the insanities of the aged are too carelessly observed in our State hospitals for the insane, that the attention to their pathology is neglected and the observation of special symptoms ignored The recoverable attacks of mania and melancholia being too often classed as chronic insanity, and the recurrent attacks of mania and melancholia in chronic cerebral atrophy classed as acute insanity

We need more attention to the study of the science mind, and less politics in our institutions to bring them up to the standard of foreign hospitals

SOME MEDICO-LEGAL EXPERIENCES IN RAILWAY CASES

Read before the Section of Neurology and Medical Jurisprudence at the Forty fourth Annual Meeting of the American Medical Association

BY THOMAS G MORTON, M D
PHILADELPHIA

Railroad injuries, from a surgical point of view, possess many features of interest, not the least of which is the medico legal question concerning the gravity or reality of alleged injuries for which pecuniary compensation is demanded

At a time when he least expects it, in these days of rapid transit and frequent travel, any individual may be obliged to witness, participate in or be the victim of a railroad accident attended by loss of life or by various degrees of traumatism—maiming, contusion or concussion, and every surgeon is liable to be called upon to render assistance to those injured or claiming to have been injured by such an occurrence Experience, however, has taught us to exercise special caution and to express a very guarded opinion as to the prognosis or gravity of a traumatism occurring under such circumstances Suits for damages are so common that the surgeon or physician almost instinctively recognizes these patients and governs himself in accordance with this fact, knowing that the attempt may be made to use him as a means of extorting large sums of money, indeed, he may even unconsciously become an innocent party to a conspiracy to defraud the railroad company defendant

Under such circumstances it would seem proper that we should consider this question, which, although largely medico-legal, is still more one of diagnosis calling for a high degree of skill to separate the genuine from the fraudulent claimants. I have prepared a brief resume of several recent cases which illustrate the tendency above referred to, but wish first to present briefly a few of the more prominent characters which distinguish this class of cases from ordinary surgical injuries. The most evident feature in these patients is a psychological one, arising from the prospect of receiving damages from a railway corporation by simple and easy means.

The fact that courts and juries are popularly believed to sympathize with the plaintiff in these trials, and the corporation defendant is popularly presumed to be guilty until proved to be innocent, has an undoubted effect in stimulating such litigation.

The number of persons in the United States annually claiming to have been more or less seriously injured upon railways is very great, many of these cases are beyond all doubt fictitious and fraudulent. Upon good authority it has been stated that English railways have paid, within a period of five years, upwards of eleven millions of dollars damages for spinal injuries alone. I believe that I am correct in stating that more or less exaggeration is present in nearly every case of railway injury. In the attempt to impress the court and excite the sympathy of the jury, very frequently the person claiming to be injured will go close to the border of imposition, even when he justly claims compensation for actual injuries. On the other hand, the willingness of railroad companies to settle such cases outside of court and to make prompt compensation for actual injuries, pain or loss of time, is so well known that designing persons attempt to take advantage of it, and cases of fraud and even actual conspiracy to defraud are not infrequent.

Prompt settlement for injuries can generally be made on more favorable and satisfactory terms immediately after the injury has been sustained, and in this way a molehill can often be prevented from growing into a mountain, because so long as the claim is unsettled, ill-health continues. In court, the possibility of permanent disability is always made a prominent feature, and every occurrence in the subsequent medical history of the claimant is apt to be traced back to the accident, as an effect to its cause.

Medical expert testimony is commonly conflicting, and the court and jury share the confusion and are embarrassed in arriving at a just verdict. Among the disturbing elements may be mentioned the fertility of the plaintiff's counsel in suggesting the dreadful possibilities of the future and his skill in painting them in lurid colors. Thus the surgical witness is often questioned concerning the possibility of cancer resulting from a contusion, or of displacement of the uterus, the development of tumors or of pelvic inflammation, all of these being the effect, perhaps, of a trivial injury whose external signs are transitory and insignificant.

Lateral spinal curvature has even been claimed to be caused in this way, which has been subsequently found to be due to congenital asymmetry of the lower limbs, as will be observed in two of the illustrative cases appended to this paper. Indeed, it would seem, in the opinions of some, that any of the ills which flesh is heir to may arise from railway injuries. The readily recognized maladies and deformities resulting from railway injuries are settled with less difficulty than cases of hysteria or neurasthenia. In these cases the symptoms, which are often purely subjective, commonly appear soon after the accident, and there is seldom any improvement while litigation continues, the injured person claims to have been in good health until the shock incident to the accident, and subsequently he is so impaired in health as to be able to attend to but little if any work of any kind. Continued nervous shock, insomnia, impaired vision and hearing, disordered alimentary and generative functions, hyperesthesia or anesthesia, general or spinal pain are prominent among the symptoms, which are indeed legion. It is not questioned that such traumatic neuroses may result from a railway shock, and without objective signs of injury, yet the increasing frequency of these cases without collateral evidence and the usual subsequent histories, naturally present the possibility of exaggeration, if not absolute fraud. At the same time such cases whether real or assumed, are very serious ones for the railway companies because of the difficulty experienced in obtaining the exact condition of the injured person, and also from the gloomy view frequently taken by the medical expert for the plaintiff, who, when pressed for an opinion as to the probability of ultimate recovery, considers complete restoration may be a matter of months or years, or the symptoms may be permanent. Generally nothing further is heard of these cases by the medical man after damages have been adjusted or a verdict rendered.

Much stress has been placed upon those injuries so-called “railway concussion” or “railway spine,” which may present no symptom immediately after the accident, but which later on develop the gravest conditions ending either in paralysis or death.

It is popularly supposed that “concussion of the spine” received in a railway collision differs from the same injury received in other ways. My colleague, Dr. Hunt, of the Pennsylvania Hospital, in which institution we have been associated for nearly thirty years, has justly said that it is absurd to give a peculiar pathological character to so called “railway spine.” That the injury occurs there is no doubt, that the medulla is seriously affected in the vast majority of cases there is very great doubt, yet the effort is constantly made to impress a jury that certain peculiar pathological results follow railway injuries and which can only be caused by such accidents.

Other structures of the spine besides the medulla are much more subjected to injury than it is, and their consequences often mislead both patient and doctor, especially the former. The ligaments and muscles are exposed to contusions, strains, ruptures and twists which are wrongfully attributed to concussion.

From these injuries, and from so called concussions the patient recovers rapidly or slowly according to their extent. If damages are looked for from a corporation, he is in a state of what may be called “*expectant pecuniosity*” and shows no amendment until the question is settled. Otherwise, he gets well, as those do who are injured but have no such expectations. There is a striking want of confirmation by postmortem examination of the terrible effects which are said to follow concussion of the spine. In fact, the records of such examinations are so few, notwithstanding the immense number of dementia or cerebral syphilis, but are distinguished from them by other associated symptoms, especially of cardiac and renal origin Vertigo is quite noticeable as before mentioned and is probably due as Hirt says, "to the atheromatous condition of the arterial walls, and the consequent irregularities of the blood supply to the brain substance"

The melancholia of chronic atrophy is, we believe, dependent alone on those circulatory changes All have noticed in attacks of acute melancholia of the aged, where cardiac disease was conspicuous, the dependence of mentality upon the stability and regularity of the heart's action In a study of probably thirty such cases, during the past four years, I have satisfied myself that more than renal disease is necessary for the melancholia of cerebral atrophy, and that the circulatory changes are, primarily, the cause of such mental depression Again, the maniacal outbreaks of chronic cerebral atrophy with their explosiveness, incoherence and destructiveness may be of cardiac origin I have noticed, especially in cases complicated with angina pectoris, that the mania was very severe and distressing The fear of impending death, to be noticed in individuals not insane is, in the insane, transposed into hallucinations and delusions, destined to cause great mental disturbance

In the ordinary senile dementia we meet with destructiveness, filthiness and incoherence, the physical and mental helplessness being but the result of the progress of disease

The decline is gradual, the slowness of the atrophic process producing mental symptoms is, at first, regarded as but the natural result of old age, the amnesia, the sudden changes in moods and emotions, and the appearance of delusions being the evolution of distinct senile dementia

The minor details are familiar to you all, and cause you more or less anxiety in their treatment, especially at their homes It is the persistent wakefulness at night of such cases and their tendency to wander away from home, that ultimately leads their friends to have them committed to the hospital Here the career of helplessness goes on until death sooner or later closes the scene In brief, I have presented the characteristics of these two *distinct* mental diseases, having *distinct* symptoms worthy of more study from alienists, especially in their pathological differentiation, which is too much ignored

Another organic disease of the brain, however not frequent, but still it does occur after sixty years of age, is paretic dementia Steadman says that it rarely occurs after fifty, but I have, in the 196 cases of insanity occurring in men over sixty, found seven marked cases Mickle has observed that "owing to the brain strain and exhaustion of the over pressure and blood deprivation in modern life, general paralysis tends to occur at an earlier age than formerly" I may therefore look upon this series of cases as of rare occurrence I rather believe in the agricultural communities, from which most of my patients came, the longevity of such people may be considered as a factor in the cases I have observed Nothing out of the ordinary was noticed in the cases, except in the postmortem examination of one, the very thin skull was interesting, for it is usual, as Wood says, to find hyperostosis and exostosis on the skull This skull was so thin that objects could readily be distinguished through it

General paralysis may occur beyond sixty years of age

Syphilitic insanity should not be confused with senile dementia, and the treatment of syphilitic insanity must be vigorously pushed in the aged to avoid chronicity

In conclusion, gentlemen, I would say that the differentiation of the insanities of the aged are too carelessly observed in our State hospitals for the insane, that the attention to their pathology is neglected and the observation of special symptoms ignored The recoverable attacks of mania and melancholia being too often classed as chronic insanity, and the recurrent attacks of mania and melancholia in chronic cerebral atrophy classed as acute insanity

We need more attention to the study of the science mind, and less politics in our institutions to bring them up to the standard of foreign hospitals

SOME MEDICO-LEGAL EXPERIENCES IN RAILWAY CASES

Read before the Section of Neurology and Medical Jurisprudence at the Forty fourth Annual Meeting of the American Medical Association

BY THOMAS G MORTON, M D
PHILADELPHIA

Railroad injuries, from a surgical point of view, possess many features of interest, not the least of which is the medico legal question concerning the gravity or reality of alleged injuries for which pecuniary compensation is demanded

At a time when he least expects it, in these days of rapid transit and frequent travel, any individual may be obliged to witness, participate in or be the victim of a railroad accident attended by loss of life or by various degrees of traumatism—maiming, contusion or concussion, and every surgeon is liable to be called upon to render assistance to those injured or claiming to have been injured by such an occurrence Experience, however, has taught us to exercise special caution and to express a very guarded opinion as to the prognosis or gravity of a traumatism occurring under such circumstances Suits for damages are so common that the surgeon or physician almost instinctively recognizes these patients and governs himself in accordance with this fact, knowing that the attempt may be made to use him as a means of extorting large sums of money, indeed, he may even unconsciously become an innocent party to a conspiracy to defraud the railroad company defendant

Under such circumstances it would seem proper that we should consider this question, which, although largely medico legal, is still more one of diagnosis calling for a high degree of skill to separate the genuine from the fraudulent claimants I have prepared a brief resumé of several recent cases which illustrate the tendency above referred to, but wish first to present briefly a few of the more prominent characters which distinguish this class of cases from ordinary surgical injuries The most evident feature in these patients is a psychological one, arising from the prospect of receiving damages from a railway corporation by simple and easy means

The fact that courts and juries are popularly believed to sympathize with the plaintiff in these trials, and the corporation defendant is popularly presumed to be guilty until proved to be innocent, has an undoubted effect in stimulating such litigation

The number of persons in the United States annually claiming to have been more or less seriously injured upon railways is very great, many of these cases are beyond all doubt fictitious and fraudulent Upon good authority it has been stated that English railways have paid, within a period of five years, upwards of eleven millions of dollars damages for spinal injuries alone I believe that I am correct in stating that more or less exaggeration is present in nearly every case of railway injury In the attempt to impress the court and excite the sympathy of the jury, very frequently the person claiming to be injured will go close to the border of imposition, even when he justly claims compensation for actual injuries On the other hand, the willingness of railroad companies to settle such cases outside of court and to make prompt compensation for actual injuries, pain or loss of time, is so well known that designing persons attempt to take advantage of it, and cases of fraud and even actual conspiracy to defraud are not infrequent

Prompt settlement for injuries can generally be made on more favorable and satisfactory terms immediately after the injury has been sustained, and in this way a molehill can often be prevented from growing into a mountain, because so long as the claim is unsettled, ill-health continues In court, the possibility of permanent disability is always made a prominent feature, and every occurrence in the subsequent medical history of the claimant is apt to be traced back to the accident, as an effect to its cause

Medical expert testimony is commonly conflicting, and the court and jury share the confusion and are embarrassed in arriving at a just verdict Among the disturbing elements may be mentioned the fertility of the plaintiff's counsel in suggesting the dreadful possibilities of the future and his skill in painting them in lurid colors Thus the surgical witness is often questioned concerning the possibility of cancer resulting from a contusion, or of displacement of the uterus, the development of tumors or of pelvic inflammation, all of these being the effect, perhaps, of a trivial injury whose external signs are transitory and insignificant

Lateral spinal curvature has even been claimed to be caused in this way, which has been subsequently found to be due to congenital asymmetry of the lower limbs, as will be observed in two of the illustrative cases appended to this paper Indeed, it would seem, in the opinions of some, that any of the ills which flesh is heir to may arise from railway injuries The readily recognized maladies and deformities resulting from railway injuries are settled with less difficulty than cases of hysteria or neurasthenia In these cases the symptoms, which are often purely subjective, commonly appear soon after the accident, and there is seldom any improvement while litigation continues, the injured person claims to have been in good health until the shock incident to the accident, and subsequently he is so impaired in health as to be able to attend to but little if any work of any kind Continued nervous shock, insomnia, impaired vision and hearing, disordered alimentary and generative functions, hyperesthesia or anesthesia, general or spinal pain are prominent among the symptoms, which are indeed legion It is not questioned that such traumatic neuroses may result from a railway shock, and without objective signs of injury, yet the increasing frequency of these cases without collateral evidence and the usual subsequent histories, naturally present the possibility of exaggeration, if not absolute fraud At the same time such cases whether real or assumed, are very serious ones for the railway companies because of the difficulty experienced in obtaining the exact condition of the injured person, and also from the gloomy view frequently taken by the medical expert for the plaintiff, who, when pressed for an opinion as to the probability of ultimate recovery, considers complete restoration may be a matter of months or years, or the symptoms may be permanent Generally nothing further is heard of these cases by the medical man after damages have been adjusted or a verdict rendered

Much stress has been placed upon those injuries so-called "railway concussion" or 'railway spine' which may present no symptom immediately after the accident, but which later on develop the gravest conditions ending either in paralysis or death

It is popularly supposed that 'concussion of the spine" received in a railway collision differs from the same injury received in other ways My colleague, Dr Hunt, of the Pennsylvania Hospital in which institution we have been associated for nearly thirty years, has justly said that it is absurd to give a peculiar pathological character to so-called "railway spine" That the injury occurs there is no doubt, that the medulla is seriously affected in the vast majority of cases there is very great doubt, yet the effort is constantly made to impress a jury that certain peculiar pathological results follow railway injuries and which can only be caused by such accidents

Other structures of the spine besides the medulla are much more subjected to injury than it is, and their consequences often mislead both patient and doctor, especially the former The ligaments and muscles are exposed to contusions, strains, ruptures and twists which are wrongfully attributed to concussion

From these injuries, and from so called concussions the patient recovers rapidly or slowly according to their extent If damages are looked for from a corporation, he is in a state of what may be called "expectant pecuniosity" and shows no amendment until the question is settled Otherwise, he gets well, as those do who are injured but have no such expectations There is a striking want of confirmation by postmortem examination of the terrible effects which are said to follow concussion of the spine In fact, the records of such examinations are so few, notwithstanding the immense number of dementia or cerebral syphilis, but are distinguished from them by other associated symptoms, especially of cardiac and renal origin Vertigo is quite noticeable as before mentioned and is probably due as Hirt says, "to the atheromatous condition of the arterial walls, and the consequent irregularities of the blood supply to the brain substance "

The melancholia of chronic atrophy is, we believe, dependent alone on those circulatory changes All have noticed in attacks of acute melancholia of the aged, where cardiac disease was conspicuous, the dependence of mentality upon the stability and regularity of the heart's action In a study of probably thirty such cases, during the past four years, I have satisfied myself that more than renal disease is necessary for the melancholia of cerebral atrophy, and that the circulatory changes are, primarily, the cause of such mental depression Again, the maniacal outbreaks of chronic cerebral atrophy with their explosiveness, incoherence and destructiveness may be of cardiac origin I have noticed, especially in cases complicated with angina pectoris, that the mania was very severe and distressing The fear of impending death, to be noticed in individuals not insane is, in the insane, transposed into hallucinations and delusions, destined to cause great mental disturbance

In the ordinary senile dementia we meet with destructiveness, filthiness and incoherence, the physical and mental helplessness being but the result of the progress of disease

The decline is gradual, the slowness of the atrophic process producing mental symptoms is, at first, regarded as but the natural result of old age, the amnesia, the sudden changes in moods and emotions, and the appearance of delusions being the evolution of distinct senile dementia

The minor details are familiar to you all, and cause you more or less anxiety in their treatment, especially at their homes It is the persistent wakefulness at night of such cases and their tendency to wander away from home, that ultimately leads their friends to have them committed to the hospital Here the career of helplessness goes on until death sooner or later closes the scene In brief, I have presented the characteristics of these two *distinct* mental diseases, having *distinct* symptoms worthy of more study from alienists, especially in their pathological differentiation, which is too much ignored

Another organic disease of the brain, however not frequent, but still it does occur after sixty years of age, is paretic dementia Steadman says that it rarely occurs after fifty, but I have, in the 196 cases of insanity occurring in men over sixty, found seven marked cases Mickle has observed that "owing to the brain strain and exhaustion of the over pressure and blood deprivation in modern life, general paralysis tends to occur at an earlier age than formerly " I may therefore look upon this series of cases as of rare occurrence I rather believe in the agricultural communities, from which most of my patients came, the longevity of such people may be considered as a factor in the cases I have observed Nothing out of the ordinary was noticed in the cases, except in the postmortem examination of one, the very thin skull was interesting, for it is usual, as Wood says, to find hyperostosis and exostosis on the skull This skull was so thin that objects could readily be distinguished through it

Syphilitic disease of the brain was observed in five cases, one made a good recovery, three died and one is still under observation The diagnosis of intracranial syphilis in the aged is difficult, but the symptoms, as outlined by Gray, have materially assisted me in making what I believe to be a correct diagnosis in the five cases above mentioned, the mental symptoms of course confirming my belief The suspicions and hallucinations being especially marked

General paralysis may occur beyond sixty years of age

Syphilitic insanity should not be confused with senile dementia, and the treatment of syphilitic insanity must be vigorously pushed in the aged to avoid chronicity

In conclusion, gentlemen, I would say that the differentiation of the insanities of the aged are too carelessly observed in our State hospitals for the insane, that the attention to their pathology is neglected and the observation of special symptoms ignored The recoverable attacks of mania and melancholia being too often classed as chronic insanity, and the recurrent attacks of mania and melancholia in chronic cerebral atrophy classed as acute insanity

We need more attention to the study of the science mind, and less politics in our institutions to bring them up to the standard of foreign hospitals

SOME MEDICO-LEGAL EXPERIENCES IN RAILWAY CASES

Read before the Section of Neurology and Medical Jurisprudence, at the Forty fourth Annual Meeting of the American Medical Association

BY THOMAS G MORTON, M D
PHILADELPHIA

Railroad injuries, from a surgical point of view, possess many features of interest, not the least of which is the medico legal question concerning the gravity or reality of alleged injuries for which pecuniary compensation is demanded

At a time when he least expects it, in these days of rapid transit and frequent travel, any individual may be obliged to witness, participate in or be the victim of a railroad accident attended by loss of life or by various degrees of traumatism—maiming, contusion or concussion, and every surgeon is liable to be called upon to render assistance to those injured or claiming to have been injured by such an occurrence Experience, however, has taught us to exercise special caution and to express a very guarded opinion as to the prognosis or gravity of a traumatism occurring under such circumstances Suits for damages are so common that the surgeon or physician almost instinctively recognizes these patients and governs himself in accordance with this fact, knowing that the attempt may be made to use him as a means of extorting large sums of money, indeed, he may even unconsciously become an innocent party to a conspiracy to defraud the railroad company defendant

Under such circumstances it would seem proper that we should consider this question, which, although largely medico-legal, is still more one of diagnosis calling for a high degree of skill to separate the genuine from the fraudulent claimants. I have prepared a brief resume of several recent cases which illustrate the tendency above referred to, but wish first to present briefly a few of the more prominent characters which distinguish this class of cases from ordinary surgical injuries. The most evident feature in these patients is a psychological one, arising from the prospect of receiving damages from a railway corporation by simple and easy means.

The fact that courts and juries are popularly believed to sympathize with the plaintiff in these trials, and the corporation defendant is popularly presumed to be guilty until proved to be innocent, has an undoubted effect in stimulating such litigation.

The number of persons in the United States annually claiming to have been more or less seriously injured upon railways is very great, many of these cases are beyond all doubt fictitious and fraudulent. Upon good authority it has been stated that English railways have paid, within a period of five years, upwards of eleven millions of dollars damages for spinal injuries alone. I believe that I am correct in stating that more or less exaggeration is present in nearly every case of railway injury. In the attempt to impress the court and excite the sympathy of the jury, very frequently the person claiming to be injured will go close to the border of imposition, even when he justly claims compensation for actual injuries. On the other hand, the willingness of railroad companies to settle such cases outside of court and to make prompt compensation for actual injuries, pain or loss of time, is so well known that designing persons attempt to take advantage of it, and cases of fraud and even actual conspiracy to defraud are not infrequent.

Prompt settlement for injuries can generally be made on more favorable and satisfactory terms immediately after the injury has been sustained, and in this way a molehill can often be prevented from growing into a mountain, because so long as the claim is unsettled, ill-health continues. In court, the possibility of permanent disability is always made a prominent feature, and every occurrence in the subsequent medical history of the claimant is apt to be traced back to the accident, as an effect to its cause.

Medical expert testimony is commonly conflicting, and the court and jury share the confusion and are embarrassed in arriving at a just verdict. Among the disturbing elements may be mentioned the fertility of the plaintiff's counsel in suggesting the dreadful possibilities of the future and his skill in painting them in lurid colors. Thus the surgical witness is often questioned concerning the possibility of cancer resulting from a contusion, or of displacement of the uterus, the development of tumors or of pelvic inflammation, all of these being the effect, perhaps, of a trivial injury whose external signs are transitory and insignificant.

Lateral spinal curvature has even been claimed to be caused in this way, which has been subsequently found to be due to congenital asymmetry of the lower limbs, as will be observed in two of the illustrative cases appended to this paper. Indeed, it would seem, in the opinions of some, that any of the ills which flesh is heir to may arise from railway injuries. The readily recognized maladies and deformities resulting from railway injuries are settled with less difficulty than cases of hysteria or neurasthenia. In these cases the symptoms, which are often purely subjective, commonly appear soon after the accident, and there is seldom any improvement while litigation continues, the injured person claims to have been in good health until the shock incident to the accident, and subsequently he is so impaired in health as to be able to attend to but little if any work of any kind. Continued nervous shock, insomnia, impaired vision and hearing, disordered alimentary and generative functions, hyperesthesia or anesthesia, general or spinal pain are prominent among the symptoms, which are indeed legion. It is not questioned that such traumatic neuroses may result from a railway shock, and without objective signs of injury, yet the increasing frequency of these cases without collateral evidence and the usual subsequent histories, naturally present the possibility of exaggeration, if not absolute fraud. At the same time such cases whether real or assumed, are very serious ones for the railway companies because of the difficulty experienced in obtaining the exact condition of the injured person, and also from the gloomy view frequently taken by the medical expert for the plaintiff, who, when pressed for an opinion as to the probability of ultimate recovery, considers complete restoration may be a matter of months or years, or the symptoms may be permanent. Generally nothing further is heard of these cases by the medical man after damages have been adjusted or a verdict rendered.

Much stress has been placed upon those injuries so-called "railway concussion" or "railway spine," which may present no symptom immediately after the accident, but which later on develop the gravest conditions ending either in paralysis or death.

It is popularly supposed that "concussion of the spine" received in a railway collision differs from the same injury received in other ways. My colleague, Dr. Hunt, of the Pennsylvania Hospital, in which institution we have been associated for nearly thirty years, has justly said that it is absurd to give a peculiar pathological character to so called "railway spine." That the injury occurs there is no doubt, that the medulla is seriously affected in the vast majority of cases there is very great doubt, yet the effort is constantly made to impress a jury that certain peculiar pathological results follow railway injuries and which can only be caused by such accidents.

Other structures of the spine besides the medulla are much more subjected to injury than it is, and their consequences often mislead both patient and doctor, especially the former. The ligaments and muscles are exposed to contusions, strains, ruptures and twists which are wrongfully attributed to concussion.

From these injuries, and from so called concussions the patient recovers rapidly or slowly according to their extent. If damages are looked for from a corporation, he is in a state of what may be called "expectant pecuniosity" and shows no amendment until the question is settled. Otherwise, he gets well, as those do who are injured but have no such expectations. There is a striking want of confirmation by postmortem examination of the terrible effects which are said to follow concussion of the spine. In fact, the records of such examinations are so few, notwithstanding the immense number of those who have claimed to have the injury, that the skeptics are somewhat justified in attributing the few cases which have shown great pathological changes in the cord and in its membranes to the coincidence of disease, as myelitis or syphilis, or to much graver injuries than concussion

I may say, after looking back upon a very large number of cases of railway injuries, real, exaggerated or feigned, upon which I have been called to give an opinion that I am not conscious that any injustice has been done in a single case On the contrary, where the claimant was judged to be a malingerer, or that fraud was attempted, the subsequent history of the case has been such as to strengthen and confirm the opinion, and on several occasions, the attempt at fraud has been confessed or the conspiracy revealed

At the present day the simulation of disease can rarely be successfully carried on, provided the medical attendant makes use of modern means of diagnosis and is familiar with the symptomatology of the feigned disease Instruments of precision enable us to attain accuracy of observation, which very promptly enables us to recognize such cases, so that fraud is detected with more certainty and its character made manifest to court and jury Impostors, therefore, are less likely to enter suit when they know that it will be contested by the railroad company and the actual state of the case brought out in testimony

In many cases, settlements are declined and consequently a defense must be made by the railway corporations, or the treasuries might at once be opened unrestrictedly to all applicants, in view of the possibility of a settlement being refused, it is important for the railways to secure, not only an examination of the injured person soon after the accident, but also an examination before the trial, such evidence may reduce a verdict, or even obtain one for the defendant Juries, however, usually sympathize with the plaintiff and can hardly be said to carefully weigh the evidence when their sympathies are aroused by the plea of mental and physical suffering or by the sight of bodily injury or deformity which is always made as prominent as possible A common method, it is said, of arriving at the proper amount of damages, is for each juryman to name his idea of the proper sum to be awarded, and these sums to be added together and divided by twelve to get the result In some instances it would seem that the last step (of dividing by twelve) had been omitted

Occasionally the gallantry of a jury is not appealed to in vain in a recent case, a husband was killed upon a track where it was shown he had no right to be Although it was agreed that the widow had no legal claim, a sentimental appeal was made simply for the widow to the jury, who gave her a verdict of $1,200 The foreman of the jury was subsequently asked how it was that such a small sum was given, when, if the widow had any claim at all, the verdict should have been at least $5,000 He replied that it was concluded that the widow could get along at least two years on $600 a year, and then, as she was good looking it was probable that she would be married, and have some one to look after her

Finally it is a curious commentary upon human nature, or honesty, but it also affords an additional argument for prompt settlement—it is commonly noticed that no matter how long the plaintiff has been a helpless invalid while the claim was pending, as soon as the settlement is made and the money paid over, he improves in health to a marked and sometimes miraculous degree

Out of the many cases I have selected the following, which are sufficient to illustrate the points which I wish especially to submit for discussion and which may be taken as representative of the entire class

In the suit brought by the driver of the coach in which said Smith was injured, he got a verdict of $6,000 We got a new trial and paid $4,000 in settlement He claimed injury to spine I afterwards saw him running across Independence Square as swiftly as a deer and as straight as an Indian

Several of the cases (4, 5 and 7) reported occurred in the service of the Pennsylvania Railroad Company, and in these the examinations were made conjointly and the opinions formulated with my associate, Prof William S Forbes of Philadelphia

Case 1—Conspiracy to recover damages from the Philadelphia Traction Railway Company for injuries self inflicted

Henry S , a young man, was standing on the platform of a Philadelphia traction car and was thrown off while rounding a curve at 5 30 in the afternoon of May 16, 1890 The lad was picked up, found to be considerably injured, and was taken to the Jefferson College Hospital, where it was found that he had sustained a fracture of the left humerus

The reports of the conductor and passengers showed that the lad was told to take a proper position, and to be on his guard at the rounding of the curve, and that there was nothing to cause him to be thrown off, as the car was about stopping This led to suspicion and an investigation, and the following was discovered

Harris P and Passa P , his son, aged 16 years, and Henry S , his son in-law, met and adopted a plan to swindle the railway corporation and concluded that one must be injured by an accident due to jerking of the car After some argument the lot fell to the son in-law, Henry S , to fall off the car on the date mentioned Henry S got on the car, stood on the back platform, and as it rounded the curve (the place agreed upon) he placed his back towards the sidewalk and deliberately stepping backwards, rolled off It was also discovered that the plaintiff had secured witnesses to observe the accident , the jealousy and cupidity of these persons divulged these facts on account of the large sum of money the plaintiff expected to receive

It was also found that Passa P , the son of the originator of the conspiracy, was present at the scene of the accident, awaiting its occurrence, and reached the hospital before the injured man arrived This led to the arrest, trial, conviction and imprisonment of the three conspirators

It was subsequently learned that Harris P , the father, had been convicted of similar crimes in Russia, and that the three had swindled other corporations in Philadelphia

Case 2—Conspiracy to defraud the Traction Railway Company

The[1] trial of the action in this case was brought by Nicola Flore against the Philadelphia Traction Railway Company to recover damages for personal injuries received, which injuries, it was alleged, were of a permanent character , a lateral curvature of the spine having resulted, and necessitated the wearing of a plaster jacket by Flore

The defense was that the claim was fraudulent and a conspiracy to defraud the company

Dr Wm Pepper, Dr Thomas G Morton and Dr Horatio C Wood were called by the defence, and taking Flore from the court-room into an ante room, they made a physical examination of his condition, first cutting from him the plaster jacket which he wore At the end of the examination they came back into the court-room and testified that they found a congenital shortening of one leg, a scar from a wound on the back near the left shoulder, and that with these exceptions there was nothing the matter with the man at all

They further testified that while making the examination they subjected him to certain tests, as to the location of pain etc , and found from his answers that he was feigning As to the plaster cast jacket, they said that, while in some instances such an appliance might be of use, there was in this case not the slightest particle of necessity for the man's wearing it

---

[1] Philadelphia Ledger November 23 1892

On behalf of Flore, a counter-conspiracy on the part of the Traction Company was alleged The counsel for the plaintiff in arguing the case for Flore to the jury, urged them to give his client $10,000 damages, while the counsel for the defendant, on behalf of the Traction Company, suggested that the jury should give Flore $50,000, the amount of damages originally laid, or, believing him to be a fraud, should give him nothing

The court, after defining the law, said "It is charged here that this case has been manufactured, that the injury has been greatly exaggerated, that the plaintiff, with the assistance of others, has attempted to deceive you and to pretend that that which was really but a trifling hurt, was in reality a permanent injury, affecting him for life If you believe that, of course your verdict ought to be for the defendant, because a man who will grossly and deliberately violate his oath and swear falsely to you intentionally, ought to be disbelieved entirely, and he is getting off very well if he goes out of court with the verdict against him It is a case for your common sense, apply it to it'

The jury, after a deliberation of about ten minutes, rendered a verdict for the Traction Company

Case 3—Trifling or simulated injury greatly exaggerated Erichsen's railway spine claimed to have resulted

Arbitration unanimously awarded a verdict for the defendant, appeal and trial before jury, who with exactly the same evidence gave a verdict for the plaintiff, an appeal to the Supreme Court and a new trial, amicable settlement effected

Mr A, a resident of Pennsylvania, stated that about 10 A M, in May, 1891, while seated in a car looking out of a window, when his body was partly turned, a sudden coupling of the cars jerked him backwards, twisting or spraining his spine He immediately rose in his place and exclaimed, 'My God, my back!'" At this time he said that he had a pain, as though something pierced him, in the small of the back, that his speech stopped to a certain extent, and became very jerky He continued his journey when the cars started in a couple of minutes or less, and on arriving at his home at noon he changed his clothing, ate his dinner, and in the afternoon went to work as usual While at work planing, his back hurt him so much that he had to quit work several times He worked several days before going to a physician, and on doing so received a strengthening plaster which he applied to his back, and continued to work, off and on, until February or March of the next year In October previous, he had applied at a general hospital for rheumatic pains

Finally a claim against the railroad was brought for a large amount of money for permanent injuries Mr A testified at the trial that he had suffered pain from the moment of the accident, that he had not the proper strength in his arms, that sleep was interrupted, there were tender spots on his back, etc The medical testimony offered by Mr A showed that his walk was impaired, he had terrible pains in his head, he was nervous and irritable, he had a swelling over the small of the back on one side, the spine was rigid as though it were a piece of solid steel, there were terribly contracted muscles, a peculiarity of speech, a jerking of his voice when attempting to speak, that when he attempts to lift his arms above a right angle with his body, he can not speak at all, that for many weeks he did not recognize any one, that he had been insane, unable to lie in bed, only on the floor, had lost control of bowels and bladder, etc In answer to a question, his medical attendant stated that he was suffering not only from hysteria, but from Erichsen's disease, or railway spine, and that he had been seriously and permanently injured by the sudden twisting of his back

An examination of the plaintiff, with Dr Charles K Mills, discovered that, although a neurotic, yet he was unquestionably a malingerer of the most pronounced type He had previously been treated for lumbago, and he had lost much time from his trade as jobbing carpenter on this account There was no evidence of spinal lesion, or that so called concussion of the spine had occurred There were some symptoms which might charitably be assigned to hysteria, but his jerky speech was purely simulation, and he attempted to deceive while testing his hearing He was of neurotic ancestry, and some of his relatives had been insane His general standing in his community was not high The settlement of the case was left by agreement to arbitrators who, after a very protracted inquiry, taking every particle of evidence obtainable, gave a verdict for the railroad company An appeal was taken from that result and the case was tried in court, and the jury, with exactly the same evidence, gave a verdict for $19,800 The company appealed and was granted a new trial, before which time came round, however, a settlement was made in full for $4,500

Case 4—Successful suit for personal injuries of alleged permanent character, plaintiff's wife subsequently confessed to a conspiracy and the entire case a fraud

W H was a passenger in a car which was thrown off the track and partly turned over by the spreading of a rail, immediately after the accident he was able to walk about, was at no time confined to his bed, and on the second day afterwards, he drove in a buggy some ten miles to see a physician Suit was afterwards brought for his injuries, and five months after the accident, an examination being allowed, the following report was made

W H stated that he had, at the time of the accident, received a wound of the thumb and also an incised wound of the ear, he also stated that a part of the seat of the car was pressed in upon his right groin His physician, who was present at our examination, stated that there had been a partial fracture of one rib, also that the patient had suffered from hemorrhages from the lungs, with some purulent discharge at such times, that there was incontinence of urine, which necessitated the frequent use of the catheter, that the testicles had been injured, that there was abdominal dropsy, as well as general dropsy of the extremities, and that he was suffering from injuries which not only had seriously compromised life but that he was also permanently injured

Upon examination, H was found to be 46 years of age, a very large man, well developed, weighed perhaps 225 pounds, he was sitting downstairs when we arrived, readily got up out of his chair, and walked without assistance or effort to the second story for our examination

The incised wound of the ear and the thumb had healed with a slight scar, the joint of the thumb had evidently been opened, for complete ankylosis had resulted There was no other evidence of injury about him, and on our asking his physician to point out the site of the partial fracture of the rib he was unable to locate the injury, and when he indicated as about the place, the latter was not where any rib existed, in other words, it was to the sternum our attention was called

There was no effusion into the abdominal cavity, nor was there any swelling or dropsical condition of the limbs There was no evidence of any lung or heart trouble In regard to the incontinence of urine, the only appearance which would sustain this was the presence of a wet spot upon the patient's shirt, but the usual indications found in incontinence were absent, in other words, there was no urinous odor about the parts, no soaked appearance of the penis and scrotum, no irritation about these parts incident to the constant presence of urine—the mouth of the urethra was normally dry With forced inspiration and expiration the testicles were elevated and depressed normally, they were of normal size and properly located, nor was there any evidence of their ever having been injured, no adhesions such as would be present had there been any local inflammation as a result of injury, the scrotum was normal The patient was apparently very sensitive to the least examination of the testicles, and complained of intense pain with the slightest examination by finger pressure When the chest and abdomen were examined by percussion (which presented no variations from the normal state) the results showed no evidence of variation from health

Conclusions The statement that the patient has from time to time more or less severe hemorrhages from the lungs and stomach is not borne out by examination, for it would be impossible for him to have such a condition without more or less disease which could be ascertained If he has any such loss of blood, it certainly is from the post nasal region and quite innocent in character, and the appearance of the discharge he is said to have would favor this view, because it is clotted and the associated discharge said to occur is probably nasal and throat mucous In other words, there is no evidence of any pulmonary or cardiac disease, which must be present to warrant any other view

There may have been some bruising of the groin, but, if such an injury did take place there is no evidence of it at this time The internal abdominal organs are normal, and the fact that the patient and his physician have been in error as regards the dropsy of the abdominal cavity and the limbs shows conclusively that a great mistake in diagnosis has been made

There are no symptoms present which indicate any permanent injury of any organ or part—in time he will unquestionably be restored to his usual health, except the ankylosis of the thumb, and some trivial scars, and further the examination warrants the belief that the case is an unmitigated fraud

The jury rendered a verdict for $16,000, and the court promptly decided to grant a new trial, or a reduction of the verdict to $10,000, the latter was accepted, and paid by the company

A year or so subsequent to the settlement, the wife of the plaintiff voluntarily came to her husband's counsel who communicated her statement to the counsel for the Pennsylvania railroad company, that her husband received only trifling injuries in the accident, that he worked for a week afterwards at his usual vocation—a butcher, peddling through the streets—and that he then conceived the idea of making a claim against the company, that he had none of the troubles which he swore to having on the trial, and that he did not dare to call her as a witness because she would have sworn that his testimony was untrue She further stated that he was not impotent, having had sexual relations with her four times during the week the trial was going on, and was also discovered with the housemaid, that he had entire control of bladder and rectum, that the blood he said was expectorated, was brought to him from the butcher, that soon after receiving the payment from the company, he went to Scotland and had not been seen since

Case 5—Lateral spinal curvature claimed to have resulted from injury, but was demonstrated to be due to asymmetry of the lower limbs

Mrs L aged 36, claimed that while sitting reading in a car she received a sudden jar induced by the coupling of a car to the rear of the train, by which she was thrown forward, striking her forehead against the frame of the window No other passenger was injured When she was examined by a surgeon soon after, no evidence of injury was seen except a slight wound on the forehead After reaching her home, some hundred miles further on, she was attended by her family physician, who stated that he found her suffering with sick stomach and severe pain extending down the spine to the sacrum These symptoms continued, the spinal pain subsequently became paroxysmal, and later on a lateral curvature was discovered, the patient, however was up and about, and gained in flesh She claimed that either walking or working aggravated the spinal pain, but she considered herself, on account of the spinal curvature, a confirmed invalid

An examination was made in 1889 for the railroad company by the late Prof Henry H Smith, who reported that

"The patient was found in bed, where she says she has remained since the accident, objective symptoms—a slight scar is apparent on the forehead, limbs are full and round, and her weight probably 170 pounds, pulse variable, showing nervous excitement, skin has a healthy color, temperature and reflexes normal, no nerve lesion Lateral curvature of long standing, possibly has been unknown to patient, physician or friends, but has no connection with the accident," and the opinion was given that the case was one of hysteria with some neurasthenia

Subsequently the claim for damages of $20,000 was supported by affidavits from various parties, among whom were female friends who testified that they had seen her dressed and undressed prior to the accident and that they had never noticed any spinal curvature and that after the accident she walked one-sided, and badly One affidavit from her pastor stated that she was "a woman of fine character and a member of his church in good standing, and the mother of five small children" A medical man testified in regard to the plaintiff "that he had never heard or seen any spinal trouble, any curvature of the spine, her walk and carriage was always straight, erect, and without trouble, nor did she have any curvature of the spine until the railroad accident"

Some months after this, Dr Smith sent in another report with his reasons in opposition to the claim that the lateral spinal curvature was the result of the accident, which condition was the principal injury for which damages were claimed This report acknowledged that a lateral curvature existed but that it certainly developed early in life, that there was no instance on record of such a curvature having developed in a few weeks by an mechanical violence whether applied through collision of cars or other force, and the creation of lateral curvature by a sudden force applied to a fully ossified vertebral column is a physical impossibility, numerous surgical authorities were quoted in support of this view But the presence of the curvature was not satisfactorily accounted for, and suit was pressed

Dr Smith died in March, 1890 As the trial was imminent, another examination was requested and allowed The patient was found to be in a fair condition of health but the main source of complaint was the curvature of the spine, which it was alleged caused pressure upon the spinal nerves and a general weakness of the extremities, and generally of all the functions

Mrs L was after much persuasion induced to permit a thorough examination of her spine, her back from her head to her heels was exposed As she stood with her back towards the window, a lateral curvature was at once observed, but at the same time the line of the nates was found oblique, and the gluteo-femoral fold of right side was much lower than on the left side, showing at once that asymmetry of the lower extremities existed, which fully accounted for the curve The right lower extremity was raised by placing books under the heel so as to equalize the limbs and the right was found to be one and one quarter inches shorter than the left With this correction of the asymmetry, the curvature vanished, and not a trace of the deformity could be found

The plaintiff's medical attendants were then convinced that the curvature was a condition of early life, and had no relation to the accident, yet nervous shock, lost time and wound of forehead were deemed sufficient to claim damages and suit for $15 000 was pressed

Just before the trial, a settlement for $2,500 was effected The plaintiff, who came walking into the room on crutches and markedly lame to receive a check and sign a release, immediately after this, got up, walked out without the crutches and without any lameness, shortly after this she was married and up to last accounts was in good health

Case 6—Action against the Philadelphia Traction Railway Company for $10,000 damages for personal injuries

On August 26, 1889, at about eight o'clock in the evening, Mrs M, a married woman, was a passenger as far as the depot in Philadelphia After safely alighting from the car, she fell on the wooden floor, some five feet away, the conductor assisted her to rise, but she claimed she was unable to walk A grocery-man near at hand had her taken home in his wagon

The woman was attended by a physician, who sent word to the company that she had broken several ribs, seriously injured her arms and legs, and as a result of the fall had aborted, and that the fetus was preserved in alcohol

The medical examiner sent by the company to make a report stated that he saw injuries upon the arms and legs, that she was plastered and bandaged in the usual manner for fractured ribs and also stated that as the doctor was a reputable physician, he accepted his statement that the ribs were broken

Subsequently the husband of the woman, and a friend, went to the office of the company and endeavored to secure a settlement for the injuries sustained by Mrs M, and for expenses incurred

The company declined to consider any proposition and suit was brought against them The severe injuries which it was claimed the woman had received attracted the attention of the legal counsel of the railroad, who, suspecting fraud, directed an investigation, which developed the following remarkable state of affairs

The woman, Mrs M, was intimate with the physician, that she had not sustained any injuries whatever, and was not pregnant at the time of her fall in the depot, that the alleged injuries on her arms and legs were specific ulcers, she had been under treatment for constitutional disease and for ulceration at one of the Philadelphia dispensaries some time prior to the accident That the fetus was obtained by the doctor from a girl of loose morals who lived in the house adjoining the plaintiff, that the doctor had produced an abortion on her when she was about four months pregnant, that another physician stated that he was called upon to stop the girl from bleeding to death after the criminal operation, that this girl was intended to be a witness in the suit for damages to prove the accident, and to state that she was a passenger on the car at the time That the husband and his friend tried to make arrangements to purchase other witnesses to testify to seeing the accident, that the two women Mrs M and the girl, picked up two men on the street, with whom they had oysters and liquor, and these men were asked to become witnesses, and were promised money for the same

It was also discovered that Mrs M was on the floor playing with puppy dogs immediately after the accident, showing that serious injury of the limbs and broken ribs were most improbable

Upon this report, the parties were all arrested and tried before Judge D Newlin Fell in the Court of Quarter Sessions, and after two full days' trial the defendants were all convicted, and were sentenced to fifteen months' imprisonment

Case 7 —Injury due to negligence of the claimant, followed by hysteria and simulated loss of power After accepting compensation, confessed to having wrongfully taken the money

Miss B stepped from the platform of a car while the latter was in motion, and in getting off faced the rear of the train, and had no recollection of stepping off, but found herself sitting on the ground bewildered The conductor came to her and said, 'Are you hurt? Can you walk? You should not have stepped off backward " Miss B , however, walked to the office of a medical man in the neighborhood, where she remained an hour and a half, was then taken to her home, and was confined to her room for some six weeks She became insomnious and lost considerable weight Some weeks after the accident she had a hemorrhage, apparently from the lungs eight weeks after the injury was walking about, went on a short journey, and after this went about as usual Damages to a large amount were claimed

On examination, Miss B , who was thirty eight (38) years of age not usually emotional, but nervous and spare frame, complained that she was unable even to do any light work, and that her health had been broken up Careful inquiry failed to detect any malady or any result of the accident, but she continually referred to compensation, and the effort was obviously made to make out the case as serious as possible

Miss B may have been somewhat contused and shocked, and subsequently became unnerved hysterical and prostrated That great exaggeration of her symptoms existed, was demonstrated when she was asked to lift one foot and then the other upon a chair, this she appeared unable to do, indeed affected not to have the power to accomplish the act Since it had been shown previously that there was no loss of muscular power, the effort to deceive was very apparent

There was no evidence of permanent injury , her nervousness was aggravated by too much sympathy by her friends of the church, who constantly condoled with her

Soon after this the case was settled for one thousand dollars ($1,000)

Some months later a lady called upon me, and seemed surprised that I could not recognize her, she then said ' Do you not remember Miss B ?" and then remarked, " I have felt as if I must see you and say that I ought never to have taken one penny from the railroad company , it was not right " And as suddenly she left

These cases are not detailed with any idea that the presentation of the facts will make any difference in future trials of railway cases, or that verdicts will in any wise be different yet it is well, perhaps, to place the histories of such cases before one another, so that we may be on guard in examinations, especially of persons who claim to have been damaged in railway accidents, whom we, from our observation, are led to believe are attempting deception

---

AURAL VERTIGO (MENIERE'S DISEASE)

Read in the Section of Neurology and Medical Jurisprudence at the Forty fourth Annual Meeting of the American Medical Association

BY L HARRISON METTLER, A M , M D
CHICAGO ILL

The classical experiments of Flourens, in which destruction of the semicircular canals resulted in unstable equilibrium, were so brilliant and apparently so conclusive that it seemed very proper to attribute the vertigo in so called Meniere's disease to the hemorrhagic obstruction and consequent interference with the normal function of these same organs Medical literature abounds with cases wherein a sudden attack of vertigo associated with loss of hearing was diagnosed as hemorrhage into the labyrinth, without further investigation into the correctness of the inference I have never felt convinced that such an explanation was the true one for the majority of these cases In the first place, vertigo is a mental phenomenon of far too complicated a character to presuppose so simple an origin In the second place, it is not positively proved that the semicircular canals preside over the maintenance of general equilibrium, for experiments have been made which indicate that they subserve in some way the purpose of hearing rather than that suggested by Flourens In the third place, neither physiological experiment nor pathological observation are sufficiently abundant to show that the canals alone are responsible for the vertigo Other intracranial structures have, in the majority of cases, been injured along with the canals And finally, the absence of any positive postmortem examination showing involvement of the canals only, forbids all dogmatic assertions in regard to them being the source of the vertigo in Meniere's disease

I will briefly consider each of these arguments and analyze a few reported cases, but before doing so I will refer to two cases that have fallen under my own observation, both of which presented the typical picture of Meniere's disease, but in which the cause of the vertigo could be easily explained otherwise than as a hemorrhage into the semicircular canals The details of my first case will be found in the *Journal of Nervous and Mental Diseases* for January, 1891, page 19

E M , a German woman, 45 years of age, having a good family history, had been subject to attacks of malaria, rheumatism, asthma and dyspepsia The pulse was rapid, irregular and tumultuous, while the sounds of the heart indicated marked insufficiency of the mitral valve, the result of an old endocarditis Being a hearty eater, the patient retired one evening in March, 1890, after indulging in a full meal, and was suddenly awakened about two hours later with a horrible nausea and distress in the stomach There was intolerable vertigo, violent vomiting and severe frontal headache The vomiting continued in the morning and the dizziness became so great that standing upon the feet was absolutely impossible The vertigo was both subjective and objective, for she beheld objects swimming about the room while at the same time she felt herself whirling about like a top It was in the morning that she first noticed the loss of hearing in the left ear The deafness was complete, but there was marked tinnitus, which the patient described as a " pounding on metal," alternating with a peculiar noise like " a group of birds in the grass " I could discover nothing abnormal with the ears externally After treatment some time with the iodid of potash, the patient improved, and consented to have her ears examined by Dr Chas S Turnbull The Doctor wrote me his opinion, which will be found with the more detailed report of the case in the journal cited The general condition of my patient, the suddenness of the attack, the unilateral character of the affection, the limited nature of the symptoms, the gradual and permanent amelioration of the vertigo, the total loss of hearing and the absence of more positive bulbar and aural signs inclined me to regard the lesion [illegible] that of an embolus in the auditory artery

My other case I saw about a year ago The woman was about forty years of age, with a good family history, and with the full phlegmatic type of constitution There was no apparent cause for the trouble, as there were no symptoms of any special disease as in the former case She was married, but childless She retired one night seemingly perfectly well, and awoke suddenly after a few hours with a roaring sound in the head, accompanied by intense nausea and dizziness In the morning she found herself totally deaf in both ears An examination of the ears revealed nothing abnormal externally Various lines of treatment proved inefficacious, and though the vertigo soon vanished and the patient regained the best of health, there was still no indication of the slightest return of the hearing In both of these cases Charcot's treatment with large doses of quinin proved entirely futile

The mental phenomenon known as vertigo, reveals upon close study, a far more complicated nature than a mere disarrangement of the function of any one organ, such as the semicircular canals The study of vertigo alone is one of the most intricate in medicine, and though we are quite familiar with its subjective and objective manifestations its immediate cause remains yet a profound mystery The maintenance of equilibrium can not be satisfactorily assigned to any single center, though its disturbance may easily depend upon a number of distant reflex disturbances There is a multiplicity of impressions constantly pouring in upon the brain through the various avenues of sensation which must necessarily keep the mind in a state of extreme tension, so that the slightest exaggeration one way or the other will result in mental confusion and more or less vertigo We learn instinctively how to control and marshal these ever passing sensations before the mind, but if for a time they become too frequent, rapid or sudden, the controlling force of the intellect is weakened and we are confused and overcome by them Everybody knows how quickly vertigo is established by rapidly revolving mirrors, peculiar whirring sounds, electrical sensations upon the skin and such distant irritative conditions as dyspepsia and constipation Physiological psychologists are agreed now that our knowledge of the relationship of things, as well as of space and its dimensions, is the result of experience gained from the use of our muscles The infant learns these dimensions by the frequent application of its hands to the objects which it sees, and the sight, which is the only other sense that reveals to us an extended object, and that never shows us more than two dimensions at one and the same time, does so entirely through the "muscular sense" exercised in the use of the muscles of the eyeball Now when we study the nature of equilibrium we discover that it is dependent upon a normal consciousness of the proper relationship of things outside of the centers of consciousness It is not purely psychic as some have imagined There is the sensation of a motor process in it Dr Hughlings Jackson has long insisted upon the importance of this fact, while Dr Reynolds wrote as long ago as 1854 that "the feeling of equilibrium results from the harmony of our different sensations among themselves and with the motor impulse which is their combined effect When any one group of the sensorial impressions is distorted or removed, the balance is disturbed and as these impressions are themselves the stimuli of muscular action, attempts are made for its restoration producing vertiginous or allied movements" The principal factors in the preservation of equilibrium are therefore consciousness and normal sense impressions A vertiginous impression reflected through consciousness may end in a complete or incomplete motor act In the latter case there is merely a residual disturbance of past impressions without a fulfillment of the present impulse in complete motion, while in the former the patient is uncontrollably moved in one direction or another

If the views of Spitzka and Starr in regard to the sensory paths in the medulla be correct, they bear strongly in favor of this sensory motor theory of vertigo Thus Spitzka concludes that impressions from the cochlea reach the cortical centers in the superior temporal gyrus by way of the posterior division of the eighth pair of nerves, the trapezium of the same size, part of the lemniscus, posterior pair of the corpora quadrigemina, external geniculate body and the corona According to some late observations of Starr which prove the correctness of the views of Flechsig and Von Monakow, the lemniscus tract is associated with the so called "muscular sense" and is chiefly distributed to the inferior quadrigeminal body Some physiologists think that it is even continued up as far as the corona It is believed that this tract is associated with the sense of sight, as well as with the coordination of movements Flourens found that injuries to the corpora quadrigemina of one side caused "forced movements," and that their complete removal resulted in incoordination of movement, yet we have no knowledge of any connection between these bodies and the cerebellum, though it is barely possible such a connection does exist At all events the point which I desire to insist upon is the close relationship of all these tracts for sight, hearing and the "muscular sense" in the corpora quadrigemina and their more distinct termination in the cerebral cortex than in the cerebellum If vertigo were a kind of encephalic ataxia, and due simply to disturbed coordination, it might readily be attributed to the cerebellum and then the *probable* connection of this part of the brain with the organs of sight hearing and muscular sensibility would easily explain the vertiginous sensations in disease of any of these peripheral end-organs While the function of the cerebellum may be that of coordination and the maintenance of "continuous tonic muscular contractions" and while as Spitzka tersely remarks, it may be the center where "impressions of touch and position are associated with those of time and space," I find no authority for assuming that it is in any way the center for the institution of movements or the maintenance of these movements in a regular, methodical manner, which, to my mind, is the underlying phenomenon, objectively or subjectively, of true vertigo Vertigo is something more than simple incoordination, though incoordination may enter as one of its principal elements In vertigo there is a disturbance, not merely of the reflex functions but of the higher powers as well The motor and sensory phenomena of vertigo, in typical cases at least, are not mere sequences of abnormal motor and sensory impulses, but they are the impulses themselves The distinction which I am endeavoring to make is the same as that between the ataxic movements of posterior spinal sclerosis and the spontaneous movements of chorea In the one case there is the retention of power, but the loss of coordination, in the other there is loss of power with or without coordination Simple incoordination manifests itself in irregular unmethodical movements and thus shows that it is due to an affection of some subordinate regulating center of the brain, true vertigo, like chorea, manifests itself in regular methodical objective movements and thus reveals disease of a higher independent center

It is a significant fact, when considered in this connection, that the vertigo which is so characteristic of cerebellar disease and which is identical with the vertigo of Meniere's disease, is caused only by lesions in the middle lobe or that part of the cerebellum which is most liable to involve the sensory-motor tract of the medulla, and furthermore, that lesions of the lateral lobes not pressing upon or involving the middle lobe do not give rise to any known symptoms And it is still more significant that vertigo is not pathognomonic of cerebellar disease, for it may be caused by lesions in other parts of the brain as well Even in its coordinating function, it is more than probable that the cerebellum, instead of sending out direct coordinating impulses to the muscles, merely coordinates the impulses sent down from the cerebral centers above Indeed, as Ranney has said, "it is a curious fact that most of the effects of cerebellar lesions are attributable, to a greater or less extent, to irritation of the crura"

According to Goltz, Serres, Cayrade and others, the function of equilibrium is profoundly affected by destruction of the corpora quadrigemina The experiments of Ferrier upon monkeys, fishes and rabbits, and of McKendrick upon pigeons, revealed the same effects The corpora striata have also been shown by physiological experiment to preside over the maintenance of equilibrium, especially after the removal of the hemispheres Every indication points to the fact, then, that we must look for the center of equilibration not in one particular part of the brain, but in the harmonious action of the various sensory and motor centers one upon another

Now for the application of all this One of the most common peripheral disturbances of this sensory-motor equilibrium is disease of the ear Hecker has said that "the ear is the most intellectual of all the organs," and in regard to its effect upon the mind, both in health and in disease, it is indeed second in importance only to the eye Without stopping to consider the many causes of vertigo in connection with the external and middle ear, I will at once consider the question of labyrinthine vertigo It is pretty generally considered now that only the semicircular canals are affected in *true* Meniere's disease At least that is what Meniere himself seems to have believed His second and fourth propositions are that certain functional troubles, having their seat in the *internal auditory apparatus*, may give rise to cerebral symptoms such as intense vertigo, uncertainty of gait, turning to the right or left and falling, all of which may be attended with nausea, vomiting and syncope, and that all this tends to confirm the belief that the lesion which is the cause of these functional troubles is in the semicircular canals In his original paper he described ten cases, in only one of which was there an autopsy This case, the tenth of the series, had no disease of the nervous centers, but the semicircular canals were filled with a "reddish, plastic material" It was on the strength of this single observation that he declared the canals to be the cause of the cerebral symptoms Aside from the unscientific character of such a hasty generalization, this one case, as Bremner points out, will hardly explain those in which the cerebral symptoms come and disappear rapidly And if the hemorrhage into the semicircular canals were the cause of the trouble here and in the majority of the apoplectiform cases, as Knapp argues, it remains to be shown why the hemorrhage should be bilateral, since the aural symptoms are so frequently bilateral

Ever since the first announcement of this affection there has been much confusion in regard to it Disease in any part of the internal ear and even of the middle ear, has been called Meniere's disease, though, as we have seen, Meniere himself was careful to restrict the lesion, in its apoplectiform form at least, to the semicircular canals Knapp, whose paper upon the subject is second only to that of Meniere himself includes all affections of the entire internal ear, irrespective of their causes, under the name of Meniere's disease I have examined his cases and fail to see why he should insist so positively upon the inner ear as the source of the vertigo and other cerebral symptoms In his third case, which he is careful to specify as a fair example of Meniere's disease, one of the most prominent symptoms was diminution of the sight—a condition which remained after many of the other symptoms had vanished After discussing in full, Voltolini's famous case in which an autopsy revealed an extensive leptomeningitis with pus at the base of the brain, in the pons, medulla and cerebellum, and some hemorrhage into the labyrinth of the ear, he makes the sweeping generalization that "the changes in the nervous apparatus of the labyrinth consequent on the hemorrhage must have been such as to destroy the hearing function forever" Thus he totally ignores the possibility, and in Voltolini's case the extreme probability, of the central injury being the cause of the deafness as well as of the vertigo and other symptoms In Politzer's case, with autopsy, there was a fissure of traumatic origin at the base of the occipital bone which probably was the cause of the meningitis of which the patient died Pain at the base of the brain was here a marked symptom Both Politzer and Lucae report cases in which the semicircular canals were absent or filled with blood, and yet the patients did not suffer from any disturbance of equilibrium In the *Lancet* of May 16, 1891, Ferrier reports the case of a man 36 years of age who was stricken with total deafness in both ears after experiencing a sound like an explosion in the head The ear appeared to be normal, and the diagnosis was hemorrhagic effusion into the labyrinth without cerebral involvement And yet there seems to have been no pronounced vertigo In most of the reported cases of Meniere's disease that I have seen, while there was a possibility of the ear trouble being the origin of the special symptom group, there was an equal possibility, and in very many of the cases a strong probability, that the more prominent symptoms were due to a central or medullary lesion, and that the aural symptoms were merely a coincident member of the group

Gowers, who is one of the strongest advocates of the labyrinthine origin of vertigo, adduces five arguments in favor of his position His first is based upon the number of cases reported by Meniere and others I have already shown how inadequate are the proofs from this source His second is, that irritation rather than mere loss of function in the nerve is proved by the disease being attended with severe vertigo, which may cease when the progress of the disease has produced complete deafness There is usually so little correspondence between the severity of the vertigo and the amount of the deafness, as Gowers himself remarks elsewhere, that this argument fails

His third is, that in the majority of the cases of definite vertigo, the slight or considerable tinnitus that is present is evidence of a process of irritation of the fibers of the nerve That is true, but the argument is no proof of the source of the irritation being within the semicircular canals or labyrinth Tinnitus is not an unusual symptom of certain extra-labyrinthine lesions His fourth argument is, that slight loss of hearing, tinnitus and vertigo may be observed not only to come on together but to pass away together I fail to see that this proves anything more about the labyrinthine origin of the vertigo than does the previous argument Lastly, he asserts that "the frequency with which symptoms of labyrinthine disease are found in cases of vertigo is itself a fact of very great significance Of 106 consecutive cases in which definite vertigo made the patient seek advice, in no less than ninety-four, ear symptoms were present, tinnitus or deafness, or more often both "

The figures are undoubtedly significant in proving the frequent association of vertigo with auditory symptoms, but they are scarcely commendable as an argument of the labyrinthine origin of the vertiginous sensation It seems to me, therefore, that these propositions, which I have presented almost in the author's own words, do not make out a very strong case in favor of the labyrinthine origin of the vertigo, certainly not sufficiently so to warrant the large percentage of cases of vertigo which this writer attributes to diseases of the internal ear

It seems to me, furthermore, that he is almost self-contradictory upon this subject He lays stress in aural vertigo upon the coincidence of the auditory symptoms with the vertigo, and shows that this is due to the continuity of structure in the cochlea and semicircular canals He says, "it is conceivable that labyrinthine vertigo may occur without any auditory symptoms I have actually seen two or three cases in which definite giddiness existed alone and in which auditory symptoms came on later " Then when I turn to his account of gastric vertigo, I find this "I do not think it is quite certain that there is such a thing as definite vertigo of purely gastric origin We know that in 95 per cent of the cases of definite giddiness a morbid state of the labyrinth is the real cause of the vertigo " This leads us to infer, then, that in 95 per cent of the cases of vertigo there are distinct auditory symptoms Few general practitioners will be prepared to admit so sweeping an assertion Would the author have us believe that in the vertigo of seasickness, which is now pretty generally attributed to the disturbance of the visual reflex, there is also a morbid state of the labyrinth? If so, his dictum in regard to the ever present auditory symptoms does not hold good here

After admitting the implication of the semicircular canals in aural vertigo, it still remains a difficult matter to explain the vertiginous symptoms and loss of hearing upon this hypothesis in all cases The first case which I have reported might easily have been regarded as one of Meniere's disease, and yet there is no reason to suppose that the vertigo and deafness were due to disease of the semicircular canals I believe that the function of these canals in the maintenance of equilibrium has been much over estimated, certainly too positively inferred in view of the slight physiological and pathological data which we have as yet for such an inference Simple puncture of the auditory nerve in rabbits gives rise to rotary movements on the part of the animal, and it is a well-known fact that injection of water into the external ear, as well as inflammation of the middle ear, causes vertiginous sensations In these cases there is present the sensory-motor disturbance, but can we suppose that in all of them the semicircular canals are so grossly affected as to be the only immediate cause of the vertigo?

Both Steiner and Sewall carefully removed the semicircular canals from the shark, whose auditory apparatus is practically identical with man's, without obtaining any disturbance of movement The former experimenter believes that the loss of equilibrium results from lesions of the brain or its membrane, causing alterations of pressure, for he has again and again destroyed the canals in sharks, frogs and lizards without injuring the brain, and discovered no disturbance in the power of equilibration After careful investigation Bottcher and Baginsky have come to the conclusion that the cause of the rotation of the head in Flourens' and Goltz's experiments was the injury done to the brain, and not merely to the semicircular canals Bottcher marks the fact that the auditory nerve is not bound down at any point between the brain and the labyrinth, and that if one is careful not to pull upon this nerve the vertiginous sensations are not awakened by the injury of the semicircular canals The slightest traction upon the auditory nerve injures its attachment at the medulla, and so gives rise to the symptoms described by Flourens, Cyon, and Goltz In the experiments of Bottcher the head, furthermore, did not always rotate in accordance with the particular canal injured, as Goltz had formulated The identity of these canals with the cochlea in the embryo, their continuity with the epicerebral space through the aquæductus vestibuli, and their ever-shifting relations amongst themselves in the quadrumana, which go about sometimes in the horizontal and sometimes in the erect position, argue strongly against the special function of these canals being the maintenance of equilibrium In the discussion of my paper upon the same subject before the Philadelphia Neurological Society, Nov 24, 1890, Dr Dercum reported some observations he had made of the comparative anatomy of the labyrinth for the purpose of securing new light, if possible, upon the function of the semicircular canals He said "They bear a distinct relation to the lateral line organs of fishes, the nerve hills of the latter being identical in structure with the maculæ acusticæ Just as the inclosure of these nerve hills in tubes seems to have for its object the gaining of distinctness and definiteness of impression, so the inclosure of the maculæ within the semicircular canals seems to have the same object It is significant that each macula is situated at the *end* of a canal and this suggests that the canal is a kind of conduit to carry off vibrations after they have made their impression on the macula, and further, that if interference of vibration occurs, it occurs at a point *distant from the macula*. Confusion of sound is thus avoided. The inference from physiological experiment that these structures have for their special object the maintenance of equilibrium, has always seemed to me open to most serious objection." It is a well known fact that many fishes have a utricle and three semicircular canals, while some have only one and two canals. Amongst the lowest vertebrates the lamprey has a saccule with auditory hairs and otoliths in communication with two semicircular canals, while the myxine or hag has only one canal. Doubtless there are important sensory impulses of a special character which pass through these organs, but equilibration, due as we have seen to the fusion of a vast complex mass of sensations pouring in upon the brain from all sides, can not possibly be the result of merely a single set of impulses from such an end organ as the semicircular canals. The very nature of vertigo involves the idea of more or less loss of consciousness, and this alone would seem to indicate a higher cause for the trouble than simply these canals.

If it be granted that the pathological cause of this vertigo is to be found in the semicircular canals, it is hard to understand how in all cases the cochlea or the cochlea branch of the auditory nerve should necessarily be affected. In Flourens' experiment, the entire removal of the canals did not impair the hearing. So striking was this fact, that Flourens as well as others was led to believe that the branch of the auditory nerve which supplies the semicircular canals subserves motor purposes only. On the other hand, if Gelle's experiments are to be trusted, the cochlea is in no way the source of vertiginous impressions. Simple continuity of structure will not account for the loss of hearing when the lesion is a hemorrhage into the canals, and pressure alone will not answer as a cause in all cases of so called Meniere's disease. In the first place, there is no regular correspondence between the amount of deafness and the intensity of the vertigo; secondly, with total loss of hearing in Meniere's disease all known methods of diagnosis prove that the nerve itself, and not merely the internal ear, is affected; thirdly, physiological experiment shows that simple pressure does not cause total loss of hearing when no injury is done to the cochlea or cochlea branch of the auditory nerve; and finally no case has ever been reported in which the cochlea was primarily affected with consequent involvement of the canals and vertigo, though in blood supply and anatomical structure the cochlea and canals are similar. Hence, in Meniere's disease, I conclude that the lesion must concern the whole labyrinth or lie entirely outside of it.

It was Dr. Wilks of England, I think, who held that Meniere's disease was a neurosis of the centers of audition and equilibrium, and in its paroxysmal form at least was much like migraine with its eye complications. While this explanation can not be adopted for all cases, there is little doubt about the central nature of the disease in many of its aspects. Burnett declared that "the neuropathic diathesis is well marked in most cases of aural vertigo." The grouping of the symptoms, as well as the proximity of the tracts and centers involved, point to the encephalic origin of the affection. Especially is this indicated, however, by the sensory motor nature of the vertigo, whatever be the peripheral source of the disturbance, and its association with the state of consciousness.

Running between the superficial and deep roots of the auditory nerve are the external and internal divisions of the inferior peduncle of the cerebellum. According to Spitzka and Edinger, the posterior nerve root transmits sound impulses, while the anterior root is the path for the impressions which assist in the determination of the equilibrium. Some of the motor fibers of the auditory nerve pass to the ampullæ of the semicircular canals, while others are doubtless associated with the anterior root in particular and the peduncle of the cerebellum. Thus the close connection between the nerve of hearing and the sensory-motor tracts in the medulla, as well as the proximity of the auditory and pneumogastric nuclei, account for the frequent association of the symptoms, deafness, vertigo and vomiting. Any disturbance, then, in the course of the auditory tract, such as in the case I have reported, is liable to give rise to Meniere's symptoms. The lesion may assume many forms, but the important point is, that it need not be necessarily limited to the labyrinth. In many of the cases reported the probability is that it was altogether extra-labyrinthine.

In conclusion, I would assert that in Meniere's disease the source of irritation may sometimes be in the semicircular canals, just as sometimes it may be in the eye and in the stomach, but that the immediate cause of the vertigo can not be there for several reasons:

1. If the above explanation of the nature of vertigo be correct it is a condition dependent upon the inharmonious interaction of the sensory motor centers of the cortex.

2. If equilibrium depended solely upon the semicircular canals, there could be no rational explanation for the ocular and stomachal vertigos.

3. If the proximity of the various nuclei within the medulla be a sufficient explanation of the association of the symptoms, vomiting, unconsciousness, vertigo and loss of hearing when the semicircular canals are affected, why, we may justly ask, do we not in stomachal, lithemic and other vertigos of reflex origin have more frequent and more marked auditory symptoms?

4. Experimental injury to the semicircular canals is not followed by true vertigo, loss of hearing and the other constant symptoms of Meniere's disease.

5. Pathological data do not entirely and satisfactorily support Meniere's hypothesis. His only case with autopsy can easily be explained upon other grounds, and nearly all of the other cases reported by Politzer, Voltolini, Knapp and others had severe cerebral lesions, sufficient to account for the symptoms presented or were unproved by postmortem examination.

Finally. It is to be noted that of Bezold's carefully collected forty six cases of necrosis of the labyrinth, only twelve manifested symptoms of vertigo.

Burnett says, "aural vertigo may be termed a reflex cerebellar phenomenon from irritation in the auditory apparatus." That may be true as far as it goes, but, from what I have endeavored to show, aural vertigo may not be aural at all, except only so far as having certain aural symptoms associated with the vertigo, and we are not justified in view of the few physiological and pathological data still at hand, in assigning all cases of vertigo with loss of hearing to an unknown and undemonstrable lesion of the internal ear

Dr Hughes—I believe that we are approaching a better explanation of the vertigo connected with Meniere's disease as well as vertigo connected with cerebellar diseases If we adopt the current explanation of labyrinthian vertigo what are we to do with the vertigo from a stomachal lesion? What are we to do with vertigo caused by irritation in other peripheral areas and what are we to do in regard to the cerebellar vertigo? Now if you look into the results of therapy in these cases, the history of cerebellar abscess as well as of Meniere's disease in connection with the treatment as it usually suggests itself, you will find that the symptoms of vertigo are very greatly ameliorated and often caused to disappear entirely under judicious treatment to diminish the irritation, of which the author speaks in his paper, which gives us unequal arterial blood supply in all probability That thing was very forcibly impressed upon me a number of years ago in a case which was reported in a journal of nervous and mental diseases, of cerebral vertigo in which the individual described had the gait characteristic of cerebellar disease had the vertigo characteristic of that disease and was disposed to walk in a circle after the manner of birds experimented on by Flourens, when he first promulgated the doctrine and gave us the cue to the characteristic symptomatology, or what we supposed to be the characteristic diagnostic symptomatology of cerebellar disease The first case in which I observed this and the beneficial results of treatment, keeping the portal circulation constantly depleted, the bowels active without fail each day, and putting the patient under bromids, and strychnia, resulted very satisfactorily, the patient was enabled to go about the streets of St Louis unaccompanied and presented the appearance of a person who was recovered, so much so that his wife believed him recovered, and yet the man actually died suddenly of a rupture into the fourth ventricle, the cerebellar abscess having found its way thither The case is on record and well known The first case that called my attention to the fact that it was possible to ameliorate and obliterate the distinctive vertigo of cerebellar disease was this, and yet the cerebellar disease persists and the same has been found true in my experience in regard to labyrinthian vertigo, and I believe that clinical observation confirms the suggestions made by the author in his paper

ADDITIONAL EXPERIENCES IN THE HYPODERMIC USE OF ARSENIC

Read before the Section of Neurology and Medical Jurisprudence at the Forty fourth Annual Meeting of the American Medical Association

BY HAROLD N MOYER, M D

Adjunct Professor of Medicine Rush Medical College Fellow of the Chicago Academy of Medicine

In a former communication [1] we called attention to the value of the hypodermic method of giving arsenic and reported some eight cases all told in which it was employed Since that time a large additional experience with the method has but confirmed our previous good opinion The list now includes twenty-eight cases of chorea, three of paralysis agitans and eight cases of neurasthenia

The hypodermic use of Fowler's solution has been recommended by numerous writers Hammond[2] claimed that the dose which could be administered in this way was much greater than could be safely administered by the mouth He says

> "I have frequently given as high as 35 drops of Fowler's solution as an initial dose It is very certain that the stomach would not tolerate this quantity Again, I have often carried the amount given by the mouth to the utmost bounds of prudence—till the eyes were puffed and vomiting almost incessant—and then have continued the arsenic in larger doses, by hypodermic injections, with the result of the cessation of all gastric symptoms and the cure of the disorder"

Dr Fruhwald[3] treated twenty two cases of chorea minor by this method He says that redness of the skin at the site of the punctures was common, and two or three abscesses formed The dose was from 5 to 20 drops, and after the use of thymol and deeper injections no further trouble was observed

Grunnach[4] treated one hundred cases of goitre with hypodermic injections of Fowler's solution, 1 part to 4 of water

Dumont[5] treated twenty six cases of goitre with injections of 10 minims of Fowler's solution

It has been noted by former experimenters who have employed arsenic hypodermically that there was a decided tendency toward the development of abscess as well as painful cutaneous inflammation These writers have invariably employed Fowler's solution and its irritating effects were attributed by some to a septic condition of the solution and by others to the spirits of lavender used to color it Prof W S Haines suggested that the irritating properties of Fowler's solution when injected into the cellular tissue was probably due to the free arsenious acid usually contained in the preparation as found in the shops, and that these might be obviated by using the arseniate of sodium, a stable salt, readily soluble and of definite composition Dr Haines recommends that the pure anhydrous salt be used, as ordinarily found in the shops it may contain from four to twelve molecules of water of crystallization If this be driven off by heating to 300 degrees the resulting salt has a definite composition with the formula $\mathrm{Na\ H\ As\ O_4}$, a 1 to 100 solution of this salt contains 53 per cent of the arsenic found in Fowler's solution, so, approximately, the dose of such solution should be about twice that of the liquor potassii arsenitis

Arsenic is one of the peculiar and exceptional remedies that is much less poisonous when exhibited beneath the skin than when given by the mouth The reason for this is shown by the fact that arsenic like several metallic poisons focuses itself largely about the upper end of the small intestine, stomach and liver, and toxic symptoms even if the arsenic is given in large doses under the skin will not appear largely in those organs Thrown into the cellular tissue it is at once absorbed into the general circulation and is distributed to all parts of the system, while if given by the mouth it may make the rounds of the portal circulation several times before entering the general circulation It is this peculiar fact that makes arsenic and mercury so much less irritating when given beneath the skin

[4] Schmidt's Jahrbucher ccx p 195

[5] Corr Blt für Sch Aerzte

The use of hypodermic injections of the arseniate of sodium is entirely free from the objections noted in the use of Fowler's solution I have given more than five hundred injections of strengths varying from 1 to 10 per cent, and have never noted any irritation, tumefaction or anything approaching an abscess Indeed, the solution is as free from irritation as is the use of simple water and any redness or slight ecchymosis following the injection is invariably due to carelessness in manipulating the syringe

The average dose of Fowler's solution given by the mouth varies from five to fifteen minims, perhaps the most usual dose is seven and a half to nine minims, and I think very few of us write prescriptions for quantities of arsenic exceeding nine minims in a single dose Of course, we may give it by the cumulative method, increasing each dose and then decreasing it, reaching nine to twelve minims, but certainly those are rather extreme doses

The quantity of arsenic in one grain of arseniate of sodium is 53-100 of the quantity found in one grain of arsenite of potassium, that is, a 1 per cent solution of the arseniate of sodium should have approximately about twice the dose of a 1 per cent solution of arsenite of potash or Fowler's solution As a matter of fact, I have exhibited an arsenic equivalent in the arseniate of sodium of 40 50, and 60 minims of Fowler's solution at a single dose, and it is my common practice to give an equivalent dose of 30 minims of Fowler's solution as my initial injection The highest that I have ever reached is the equal of three quarters of a grain of the arsenite of potash, that is, equivalent to 75 minims of Fowler's solution at a single dose and this without producing more than the slightest toxic effect

I think that the method is worthy of more extended trial, and it certainly in my hands has given exceptional results in the treatment of chorea I have not found it to be of any value in paralysis agitans or cases of neurasthenia in which I employed it, but in chorea it has certainly exceeded any drug I have employed heretofore, and has far exceeded in efficiency and in cutting short the duration of the disease, the employment of the Fowler's solution by the mouth, this I attribute of course to the larger dose given and the fact that the salt is brought immediately in contact by the blood with the nervous system without having first passed the liver

We certainly hope that while this method is so free from inconvenience and the drug is of such power that we shall hear of its use in malarial affections and in diseases of the skin In these latter disorders we should certainly expect to hear of better results than have been reached in neurological practice

DR J F HIBBERD—I suppose the doctor has met with some failures in his treatment What proportion do the failures bear to the successes, if there be observations which would enable him to make that statement? I perhaps am now particularly interested in the matter because I have a family of choreic people, the father and mother have had it the two daughters have had it turn about for two or three years, and I have tried about everything that I have known of others using with any success, but I think with all of them that the affection wears out, that is a good thing, sometimes, however, it does not wear out, but keeps on, but if your preparation of arsenic and soda will shorten the period of duration, even if it does nothing that we can measure accurately, it will be of great benefit to the general practitioner

DR DANIEL R BROWER—I know nothing specially about the use of the arseniate of sodium hypodermatically as Dr Moyer suggests, but I have no question as to its value from his statements, but I desire to testify to the fact that the arseniate of sodium is a very much better remedy to use in the treatment of chorea given by the stomach I have been for years using the liquor sodii arsenatis, because the soda salt of arsenic is very much better tolerated by the stomach, and I have succeeded in giving by the stomach without discomfort to the patient, without toxic symptoms, sometimes doses double the size that could have been given of the arsenite of potassium I am speaking, of course, of its administration by the mouth, and given in this way I have found it a very valuable aid to the general treatment of chorea Speaking about the treatment of chorea, I have had some recent experiences with the line of treatment suggested, I think, by Dr Wood of Philadelphia, the use of quinia in large doses, and two or three recent cases that have come under my observation have done surprisingly well with moderate doses of the arseniate of sodium and very large doses of the bromid of quinia I believe there is some advantage in the use of the salts of cinchona, especially the bromid of quinia, in the treatment of chorea I think the combination of the bromid with the arseniate either hypodermatically or by the mouth, is certainly quite an advance in the therapeutic treatment of chorea

DR C H HUGHES—I do not believe that arsenic is the best cure for chorea I know it is the fashion to laud arsenic as the remedy for chorea, but I have not found it as efficient in my treatment of cases as I have the moderate doses of Fowler's solution in connection with the bromid of quinia and the hypophosphites—that is the combination I always use, and I think six weeks is the limit to 90 per cent of my cases during the last twenty years I do not believe I recall a case in my practice now, a recent case, at least, that did not recover, with rest and this line of treatment, by the expiration of six or eight weeks Some cases recovered in four I have never adopted what I consider the fad of relying exclusively upon arsenic, and in regard to the use of quinin, it never occurred to me to omit the use of quinin in certain obstinate cases of that disease in the Mississippi valley I suppose it was because malaria entered into the disease as a complication, and it became necessary to eliminate that factor, as it is in so many diseases that we encounter in our practice in the vicinity of St Louis I have given very large doses of quinin in the course of treatment of chorea where I had reason to suspect there was a malarial complication or latent malaria as one of the depressing toxic influences operating upon the central nervous system, and I suppose that when the facts are fully learned, it will be found that those cases that yield so readily to quinin are those in which the chorea is really of malarial or toxic origin

Now regarding the chloral treatment, you know that that plan has been pursued exclusively, so has the arsenic treatment and so has the iron treatment Dr Hughes of England, used port wine and rhubarb, taking the children out of school and giving the necessary rest, and he cured his cases My experience is that the majority of cases will get well, if you remove the pressure that has been on the child, remove the source of depression, of irritation, take the child from school, return the child to childish ways and natural habits of life that belong to children, and improve its nutrition, and you have very little need of the arsenic goes, but, from what I have endeavored to show, aural vertigo may not be aural at all, except only so far as having certain aural symptoms associated with the vertigo, and we are not justified in view of the few physiological and pathological data still at hand, in assigning all cases of vertigo with loss of hearing to an unknown and undemonstrable lesion of the internal ear

DR HUGHES—I believe that we are approaching a better explanation of the vertigo connected with Meniere's disease as well as vertigo connected with cerebellar diseases If we adopt the current explanation of labyrinthian vertigo what are we to do with the vertigo from a stomachal lesion? What are we to do with vertigo caused by irritation in other peripheral areas and what are we to do in regard to the cerebellar vertigo? Now if you look into the results of therapy in these cases, the history of cerebellar abscess as well as of Meniere's disease in connection with the treatment as it usually suggests itself, you will find that the symptoms of vertigo are very greatly ameliorated and often caused to disappear entirely under judicious treatment to diminish the irritation, of which the author speaks in his paper, which gives us unequal arterial blood supply in all probability That thing was very forcibly impressed upon me a number of years ago in a case which was reported in a journal of nervous and mental diseases, of cerebral vertigo in which the individual described had the gait characteristic of cerebellar disease, had the vertigo characteristic of that disease and was disposed to walk in a circle after the manner of birds experimented on by Flourens, when he first promulgated the doctrine and gave us the cue to the characteristic symptomatology, or what we supposed to be the characteristic diagnostic symptomatology of cerebellar disease The first case in which I observed this and the beneficial results of treatment, keeping the portal circulation constantly depleted, the bowels active without fail each day, and putting the patient under bromids, and strychnia, resulted very satisfactorily, the patient was enabled to go about the streets of St Louis unaccompanied and presented the appearance of a person who was recovered, so much so that his wife believed him recovered, and yet the man actually died suddenly of a rupture into the fourth ventricle, the cerebellar abscess having found its way thither The case is on record and well known The first case that called my attention to the fact that it was possible to ameliorate and obliterate the distinctive vertigo of cerebellar disease was this, and yet the cerebellar disease persists and the same has been found true in my experience in regard to labyrinthian vertigo, and I believe that clinical observation confirms the suggestions made by the author in his paper

ADDITIONAL EXPERIENCES IN THE HYPODERMIC USE OF ARSENIC

Read before the Section of Neurology and Medical Jurisprudence at the Forty fourth Annual Meeting of the American Medical Association

Now regarding the chloral treatment, you know that that plan has been pursued exclusively, so has the arsenic treatment and so has the iron treatment Dr Hughes of England, used port wine and rhubarb, taking the children out of school and giving the necessary rest, and he cured his cases My experience is that the majority of cases will get well, if you remove the pressure that has been on the child, remove the source of depression, of irritation, take the child from school, return the child to childish ways and natural habits of life that belong to children, and improve its nutrition, and you have very little need of the arsenic treatment I think in a large majority of cases that time alone will effect a cure, I will not say despite the arsenic, but I will say that time and rest are the essential remedies and those remedies which conduce to rest of the central nervous system are the important factors, that is why we get cures from chloral given every night and in the daytime as some of our German friends do That is why you get it from giving the child a vacation, taking it away from school, giving it a change of scene One of my patients was cured within the last six weeks on a very simple prescription The child took a vacation and went off to Texas and got well by traveling

The Chairman—I would call attention to the fact that the principal point of this discussion is the hypodermic use of the arseniate of sodium

Dr Frank R Fry, of St Louis—I think the doctor has fully demonstrated the advantage of his method I have used the arsenic hypodermically, though I have never used Fowler's solution in that way, but a solution of equivalent strength made aseptically, and I have had a great deal of irritation from it, though I have never had an abscess, but so much irritation that I have abandoned it long ago in the majority of cases, only occasionally employing it when the stomach was absolutely intolerant, and therefore I can corroborate the statement that the doctor has made that it is not the aseptic properties nor the irritating properties of the lavender water or spirits of lavender in the solution that make it irritating, but the salt itself Furthermore, in having these solutions prepared I was always careful to get a chemically pure salt

Dr Elmore S Pettyjohn—These cases are usually found in young persons, and there might be a great deal to overcome in giving these injections How does the doctor manage that matter to the satisfaction of his youngest patients?

Dr Moyer—I regret, since the discussion has taken the range that it has, that I have not here to present to you some of my clinical histories I did not at first desire to burden this Association with an account of a lot of choreic patients I conceive that we all see a vast number of them, but I will say to the gentleman who first made some inquiry that I have treated inveterate chorea and the recurrent chorea and chorea in its chronic forms, and I have treated acute chorea, in fact all varieties by this method Of course the value of any therapeutic measure depends upon the experience of the man that proposes the method, and I can not bring you anything to support it more than my individual assertion I have treated 500 cases with arsenic given by the mouth and 28 by this method, and I am absolutely surprised and amazed at the results that I have obtained I certainly think that the average duration of treatment has been very much less than six weeks I do not think that under this method it has averaged over two weeks I fully agree with Dr Hughes regarding many things in the treatment of chorea It is a self-limited disease, it is a disease whose natural tendency is to get well whether you employ treatment or whether you do not, the patient will get well in the great majority of instances, but I contend that in my experience, specific treatment is useful, and of all methods arsenic is by far the most useful and of all the arsenic methods the hypodermic use of the drug is the best You can get a much larger quantity into the patient's system without any toxic effect, and you produce a very profound impression indeed, and it has not been an infrequent occurrence with me to have the choreic movements lessen or cease entirely within three days I understand that there are a great many hygienic measures that can be employed in the treatment of chorea in the better class of patients, but the majority of my cases are out patients in a large dispensary, seven to fifteen years of age, the disease rarely affecting those below the seventh year, and I have been wholly unable to control their diet, and habits of living, many of them are children employed in factories and shops, belonging to the lowest classes in a large city, and it is among this class of patients in which you can do nothing for them except what you do medicinally that I would above all things recommend the trial of the hypodermatic use of this drug

Regarding Dr Pettyjohn's question, I would say that the patients perhaps object to it—the little ones do—those that are eight or ten do not seem to care very much The younger ones you simply take by the arm, the mother holds the other hand, and you give them the injection, that is all there is to it If they cry a little, why let them cry, but as a rule I have not found much difficulty in giving injections, even in quite young children The slight prick may be objected to at first, but after one or two injections they generally do not care very much about it

---

THE FUNCTION OF THE RIGHT TEMPORO-SPHENOIDAL LOBE

Read before the Section of Neurology and Medical Jurisprudence at the Forty fourth Annual Meeting of the American Medical Association

WM J HERDMAN, Ph B, M D
ANN ARBOR MICH

In an authoritative work on "Diseases of the Nervous System" recently published, the temporal lobe of the brain on the right side in man is spoken of as one of the "latent regions of the brain, destruction of which, and irritation of which, produce no special or distinctive phenomena" Clinical and pathological evidence bearing upon the functions of the temporal lobes is acknowledged to be scanty at present by no less a specialist on this subject than David Ferrier, and the discrepancies in the results of the many experimental researches upon animals conducted by him, Victor Horsley, and other observers of undoubted merit, cause us to welcome any additional light, however meager, that will aid in clearing up the darkness that still surrounds this region of the human brain

A most novel and interesting case recently came under my observation in consultation, which terminated fatally within five weeks from the beginning, and in which I had the good fortune to obtain an autopsy, that may in some small degree add to existing knowledge as to the part taken in cerebral action by the right temporo sphenoidal lobe

Mrs G F, a native of Michigan, 45 years of age, spent the greater part of her life on a farm and was always a hard worker Her constitution and general health had always been good although she was not robust She has given birth to two children the younger now being 15 years of age A few years prior to her last illness she consulted an oculist for a slight impairment of vision in the left eye but it never gave her much trouble She never had rheumatism, gout, syphilis, cancer or any other serious disease or injury, but she has been a sufferer from headaches for many years Her father died suddenly, presumably of heart disease in some form Two of her uncles have died of brain trouble and a sister has epilepsy-gravior, two sisters are subject to severe headaches Her habits and modes of life were always exceptionally good and regular and her hygienic surroundings were always of the best She was of a lively and sociable disposition, active and efficient in her circle of acquaintance and much employed with church and Sunday school work About five years ago she changed farm life for village life and has for four years successfully managed the finances of a moderate estate which devolved upon her at the death of her husband

On April 3, 1893, while about her household duties she felt dizzy and sick at the stomach, and she stated to her son who came into the house soon after and found her lying on a couch, that she had fainted in the kitchen and after regaining consciousness which could have been absent but a few moments, she had without assistance walked into an adjoining room and laid down on the couch While talking with him she had what seems to have been a spasmodic seizure,and again became unconscious Her physician was summoned who on arriving within half an hour found her with all muscles relaxed except the inferior recti which seemed to be contracted The heart's action extremely feeble Ammonia carbonate was injected hypodermically and nitrate of amyl applied to the nostrils In about twenty minutes some signs of improvement were noticed in the circulation and at the end of three hours the pupils returned to normal condition She would then swallow liquids placed in her mouth if requested to do so by speaking loudly close to the ear (right)

There was no motor paralysis attending or following this condition for she freely moved both arms and legs, and there was no disturbance of the facial expression, but the intellect was profoundly clouded

April 4 —Spent a restless night, respiration moaning and sighing, with an occasional exclamation of "Oh dear," but no satisfactory response could be gotten to the inquiries as to the cause of her distress Temperature 101, pulse 100

April 5—Slight improvement in the intellect but still unable to recognize those about her Kept carrying her hands to her head and exclaiming "Oh my head," at frequent intervals The distress in the head seemed to be constant and mainly over the left frontal region She took nourishment when it was given to her but gave no sign of recognizing the need of it Very restless, tossing herself about in the bed Temperature and pulse the same as the day before

April 6 —Some improvement, answers when spoken to but often irrelevantly Complains of severe pain in frontal region Temperature 100, pulse 94

April 7 —Further return to consciousness, calls friends by name but with some hesitancy Seemed to have no memory of what had happened and expressed surprise when told she had been sick, said if it were not for her headache she would be quite herself again Headache constant and frontal, other symptoms remain unchanged

April 8 —No change, still restless and severe headache

April 9 —Headache less severe, mental conditions still further improved, more mental activity but attacked by hallucinations, able to recognize friends Temperature and pulse normal She was given a dose of castor oil which ordinarily was extremely disagreeable to her and swallowed it without remark In health the taking of castor oil was a thing she declared she could not do Afterwards when reference was made to it, she remarked that she must have been very sick if she took castor oil and did not complain of the taste

April 10 and 11 —Headache less acute and constant, mind clearer, she called to mind events that had occurred and began to take interest in the household duties, still troubled with hallucinations, but they were of a pleasant type and she laughed when relating them

At this time it was noticed that, although her mind had regained its activity, hearing on the left side was dull and confused, as she expressed it she "heard double"

April 12 —Began to sit up a little, headache not constant Hallucinations of being away from home, out in company and having a good time

April 13, 14, and 15 —Very little change except gradual improvement, less aberration of the mind Sat up a good portion of the day

April 16 —All pain in the head gone, mind clear and she felt quite like herself, got up and dressed and was about the house all of the day Much pleased at the visits of her friends Laughed and joked with them and they could not see but that she was quite well She took her meals at the table with the family With the exception that her hearing was imperfect especially upon the left side, and the taste remained blunted, there was at this time no evidence of sensory, of motor or mental disorder

This marked improvement continued until April 22 She planned to resume her household duties and discharged all attendants and appeared quite like her natural self No abnormality in mental action or in movements were observed by anybody about her

April 22 —The attending physician was again summoned, found her complaining of much frontal headache The temporal arteries were distended, but there was no abnormal action in the pupillary reflexes, nor was there any confusion of the mind He was again summoned on the night of the 23d and found her unconscious respiration slow, pulse feeble, pupils normally dilated No marked spasm of any muscles Cardiac and respiratory action soon improved and after a few hours she could be so far aroused as to be induced to take liquids and swallow them

April 24 —Still comatose but could be aroused somewhat by loud talking Temperature 101 Pulse 96, respiration 24

April 25 —Condition unchanged except the coma was not so pronounced She would often carry her hand to her head exclaiming "Oh my head"

April 26 —Condition much the same, except at intervals she recognized members of the family about her

April 27, 28 and 29 —Gradual improvement in the mental conditions, intellect sluggish and unable to fix her mind for any length of time upon any subject Eyesight normal with the right eye but with the left unable to count fingers at a distance of twelve inches Complained of much headache and some pain in the base of the brain, took abundant nourishment

In the afternoon of April 30, the nurse discovered that the left side was paralyzed throughout, the facial muscles and the tongue being involved, she was unable to turn the left eye outward Involuntary actions of the bowels and bladder

May 1 and 2 —Remained the same, speech and swallowing imperfect The patient was left handed

May 3 and 4 —Improvement in speech and swallowing, and began to get voluntary control of the left arm and leg

May 5 —Respiration normal, some voluntary control over the action of bowels and bladder regained Still some disturbance of speech and deglutition and the face remained slightly drawn to the right The tongue when protruded turned to the right, was red and clean Vision much improved in left eye and right eye normal Left eye can not be turned outward, mental action dull, but able to recognize friends Thoughts disconnected and disjointed She was able to sit up in bed for a few moments and to move from one side of the bed to the other

May 6 —Continued to improve Took nourishment readily Strength in right arm and hand increased She was able to grasp the hand of the nurse quite firmly Eyes normal in appearance but the left still impaired in action of external rectus Vision unchanged The temperature on this and other days after April 30 did not exceed 99½ Speech was now quite distinct Mind clear but inactive Headache which had been light returned with great violence towards evening

May 7 —Passed a restless night, manifesting more than her usual timidity Clung closely to the nurse Had several general convulsions in the morning from 8 30 to 9 30 during which the left eyelids were open and the pupil contracted The pupil of the right eye was widely dilated, the lids closed The headache seemed very severe as evidenced by her moaning and carrying her hands to her head after the convulsions ceased Stupor followed the convulsive seizures and gradually deepened into coma, though consciousness was retained long after she was able to utter a sound Hearing was not abolished up to within an hour or two of death for she would squeeze the nurse's hand in response to inquiries uttered in a loud tone, but she lay upon the bed in such a manner that she could not be approached only upon the right side, and hearing upon the left side was not tested during the last weeks of her illness

NECROPSY

Eighteen hours after death Skull unusually thick Dura mater congested and apparently thickened Superior longitudinal sinus empty, veinous congestion of the pia mater, the arteries moderately full No naked eye appearance of special abnormality about the frontal lobes, although the anterior cerebral arteries seemed somewhat more anemic than others A clot of dark semi-coagulated blood about two inches in diameter occupied the right middle cornu, and the walls of this cornu were extensively disintegrated and readily gave way The disintegrated tissue involved the anterior half of the hippocampus, the anterior extremity of the superior temporal and the anterior third of the middle and inferior temporal gyri The gyrus hippocampus was largely undermined although its surface remained intact The island of Reil was softened Blood coagula more or less firm and recent in formation, filled the lateral ventricles the third ventricle and the infundibulum, and extended through the aqueduct of Sylvius into the fourth ventricle No softening or disintegration had taken place except in the right temporo sphenoidal lobe The time being limited other cavities of the body were not explored

I need scarcely say to you who have been able to follow me in this hurried recount of bedside observations, that the revelations of the autopsy were something of a surprise to me In the light of the discoveries then made I was compelled to admit to myself that I had, in constructing a theory of causation of the clinical phenomena observed, placed too much stress upon certain prominent symptoms I saw the patient twice for about half an hour each time On the first occasion, the suddenness of the onset of the symptoms, the mental confusion, the severity of the headache, which was frontal and left-sided, the impairment of vision of the left eye, the entire lack of motor and sensory abnormalities (for this was at a time when she was beginning to recover from the first attack) impressed me quite forcibly, and I was confident there was an arterial embolus obstructing the left anterior cerebral artery The subsequent complete clearing up of the mental cloudiness and the subsidence of all other symptoms only confirmed me in this opinion The only thing that was suggested to my mind that threw doubt upon this conclusion was how to account for the dullness in hearing in the left ear But in the apparent harmony of the more prominent symptoms in accord with my theory, this did not seriously attract my attention The perverted or impaired taste was not an observation of my own, but was a fact learned from inquiry of the attendants subsequent to the autopsy The theory of embolism seeming to account for the symptoms following the first attack, the phenomena attending the second attack, which occurred after twenty days, and when many of the disturbances resulting from the first had subsided, presumably because of some degree of collateral circulation being established, were accounted for on the assumption that a thrombus had formed posterior to the embolus and its backward growth had, in all probability, crossed the anterior communicating artery and suddenly plugged the other anterior cerebral, as at this time, you will observe, there were no spasms, no paralysis, simply an obscuring of mental faculties which again largely cleared up within a few days

The autopsy revealed that the original attack had been due to a hemorrhage, not very extensive, interior to and at the lower extremity of the right lateral cornu Softening followed, involving the hippocampus major at its lower extremity, the anterior extremities of the superior middle and inferior temporal convolutions

The hemorrhage from its location might have caused pressure on the optic commissure, especially its left side, together with interruption in the circulation through the anterior part of the circle of will in rendering the anterior cerebral arteries anemic At the second attack the hemorrhage, still more extensive and far reaching, had extended into the lateral ventricles and the third, even passing into the infundibulum and distending it, causing pressure on the pituitary gland The third attack, from which she never rallied, was attended by an escape of blood from the same source, but in addition to flooding the lateral and third ventricles it had passed through the aqueduct of Sylvius into the fourth ventricle

I think we are justified in the assumption that as far as any symptoms observed in this case can be justly referred to the lesion in the right temporal lobe, they tend to show that its function is of the same nature for the left side of the body that Ferrier has found the left temporal lobe to be for the right, a cortex center for hearing and taste

My experience in this case has impressed upon me more strongly than ever the necessity of a systematic and thorough examination in detail of all the sensory and motor tracts in every case of central lesion, and that according to a definite plan should, wherever circumstances permit be rigidly carried out, even through certain symptoms may seem to show that such extended investigation is superfluous

DR KIERNAN—As Dr Herdman has indicated in the first part of his paper, it is well known that lesions of the right temporal lobe give fewer special symptoms than lesions in any other part of the brain It is in some respects the almost latent region of the entire brain Doubtless it has its functions The doctor has suggested in his paper that the functions of the right temporal lobe are the same for the left side of the body as the left for the right, but the functions of the left temporal lobe, at least the principal part of the left temporal lobe, are largely for hearing, which is not a function for either the one or the other side of the body, and in many cases the left half or left side of the brain in certain functions, acts for both sides of the body It is interesting, however, in this case, to note that the patient was left handed Now, ordinarily, I have no doubt, that while the right third frontal convolution and the right upper temporal convolution and the temporal convolutions generally are comparatively latent, yet they are centers for these functions potentially, before the left side of the brain is developed Here it would seem to me to be the reasonable explanation that probably both the right third frontal and the right upper temporal, in accordance with what we find in left-handed cases, had taken on the functions of the left side of the brain more largely than is usual I have had several cases of lesion of the right temporal lobe One of the most interesting cases that I have ever seen is recorded in my paper on cerebral localization, and it was also reported by Dr H C Wood, whose case it was in fact It was originally a case of tumor of the right temporal lobe This tumor grew and radiated in various directions Finally hemianopsia and other symptoms indicative of lesion of the occipital lobe were present, and then Dr Wood in consultation with ophthalmologists and Dr Agnew, decided on an operation, and the patient was trephined over the occipital lobe of the right side The patient latterly had lateral hemianopsia Dr Agnew came down on really a radiation of this tumor, but doubtless that which produced the hemianopsia The patient died, an autopsy was made I saw the specimen which was an immense tumor involving the entire right temporal lobe, or very nearly so, and thence had grown backward into the occipital lobe There was a record of observations of this patient for a long time which showed that this tumor had been in the lobe with some development for a long time, but the practical point about it was that the lobe usually, so far as we know, is latent in symptomatology and that both neurologists and surgeons should pay very strict attention to the possibility of symptoms indicative of occipital or other lesions being really the symptoms of the final development of a right temporal lesion I had one other case which I have also reported, a glioma of the right temporal lobe, the patient dying from intercurrent hemorrhage

LAWS OF GROWTH OF BACTERIA APPLIED TO ASEPTIC SURGERY

Read before the Section of Military Surgery, Pan American Medical Congress, September 7, 1893

BY ROBERT REYBURN, A M, M D

PROFESSOR OF PHYSIOLOGY AND CLINICAL SURGERY MEDICAL DEPARTMENT HOWARD UNIVERSITY WASHINGTON D C

It has been well said by a great operator that every surgical operation is a study in bacteriology There will be found, we believe, at the present day very few surgeons who will gainsay the above statement, and yet it may be worth our while to examine the question whether our surgery, as practically carried out, is in perfect accordance with the laws of bacterial growth which are the underlying basis upon which aseptic surgery has been built To return to elementary principles let us inquire what are the three essential conditions favoring the growth of bacteria and other microorganisms? The answer, of course, that would be given by every tyro in surgery would be the well worn statement heat, moisture and atmospheric air In other words, the very same conditions which favor the growth of bacteria are precisely the same conditions that are essential to the growth and repair of all the tissues and organs of the human body

The logical sequence of this results in the following statement, viz That no treatment of the tissues or organs of the body involved in surgical operations can be successful, which seeks by the action of powerful chemical agents to destroy bacteria in and around wounds, for if powerful enough to accomplish that object, the tissues themselves must be destroyed or injured

A surgical operation is to a certain extent the opprobrium of medicine, for in having recourse to it we thereby confess the failure of our science The ideal surgical operation, therefore, is one that removes the diseased or injured portion of the body with as little disturbance of the normal conditions of the tissues as possible Repair without inflammation is, as all know, the motto of modern surgery How preposterously absurd, therefore, is it for us after having removed, let us say, a tumor or limb from the body, to douche the seat of the operation with solutions of mercurial chlorid or other powerful irritant, producing necrosis of the tissues and thus preventing the very end we seek to attain

Notwithstanding the profound respect that all surgeons feel for the work and self-denying labors of Sir Joseph Lister, yet there can be no questioning the fact that the theory and practice of antiseptic surgery are rapidly being abandoned, and the more perfect science and art of aseptic surgery are being substituted in its stead

To Prof Lister we owe the grand idea of excluding the bacteria and other germs from wounds, thus creating the new science of antiseptic surgery It is perfectly true that aseptic surgery, as now practiced in this country and in Europe, is very different from, and far superior to, the cumbrous procedures and dressings devised and practiced by the father of antiseptic surgery The carbolic spray, once universally applied, has been almost entirely abandoned, and during my recent visit to Europe I never saw it once used The many layers of protective gauze, mackintosh, etc , are now replaced by a simple layer of iodoform gauze, with an abundant layer of aseptic cotton firmly retained by bandages

Another remarkable change is the growing disbelief in the efficacy of the ordinary antiseptic solutions when used as germicides A solution of carbolic acid has been shown to be a weak germicide, and the same may be said of a solution of boric acid and of the other solutions used commonly for this purpose Mercuric chlorid has until the present time been our sheet-anchor as a germicide As we lost our faith in one germicide after another, we thought we could rely on that Yet the iconoclasts are busy in their work of tearing down all idols in medicine, and now they have not left us this one Recent investigations carried on at Johns Hopkins University (published in the Johns Hopkins *Hospital Bulletin* of April, 1891, pp 50–60), by Dr A C Abbott, on "Corrosive Sublimate as a Disinfectant against Staphylococcus Pyogenes Aureus," on page 59, at the close of a very elaborate series of investigations on this subject, he says "It is seen that under the most favorable conditions, a given quantity of corrosive sublimate has the property of rendering inert only a given certain number of individual organisms " Ibid, page 60, he summarizes his results in the following words "In the light of these experiments and those of the experimenters quoted in this paper, it is plain that for use in surgical practice, the solutions of corrosive sublimate do not possess all of the advantages hitherto attributed to them To the employment of the sublimate solutions upon wounded surfaces it is plain there exist at least two serious objections First, the albumen of the tissues and fluids of the body tends to diminish the strength of, or indeed renders entirely inert, the solution employed, and second, the integrity of the tissues is materially injured by solutions of this salt '

Investigations made at the University of Michigan (published in the *Medical News* of October 1 and 8, 1892), have shown that solutions of mercuric chlorid when used as a germicide are often inert, and still oftener actually injurious to the tissues, when applied during surgical operations

Dr Charles T McClintock gives in the above paper (*Medical News*, October 8, 1892, p 399), the following summary of his experiments, viz

"1 The high rank heretofore given to corrosive sublimate as a germicide is without warrant and was based on faulty experiments

"2 The very varying power of resistance in different cultures, as pointed out by Esmarch and insisted on by Gruber, is an all important factor to be noted in determining the germicidal power of any agent

"3 That sublimate forms with cellulose, as cloth, filter paper, etc , with silk, with albuminous bodies, with some part of bacteria (probably the envelope), a chemical compound that can not be removed by any amount of washing with water

"Thus the sublimate, when acting upon a germ, forms a capsule around it that protects the germ for the time from the further action of the sublimate, and in turn forms an impenetrable barrier to the growth of the organism unless it be removed This barrier may be removed with salines, and is more rapidly removed in proportion to the renewal of the salines, conditions that are fulfilled in the circulating blood

"The above named experiments would seem to warrant the expression of the opinion, that the use of solutions of corrosive sublimate in surgical operations should be limited to the cleansing of the surface of the part to be operated on, and to the disinfection of the hands and arms of the surgeon, and furthermore, that such solutions should never be applied to surfaces denuded of epithelium, or cut surfaces of the body made during surgical operations ”

Antiseptic surgery endeavors to destroy the micro-organisms in and around the wound, and thus prevent their development How futile this effort must be, when we consider that these organisms are everywhere and at all times present with us They are in every breath we draw, in much of the water and in many of the articles of food that we consume, and indeed, exist always in the alimentary canal and all parts of the body exposed to the air But on the other hand, it must be remembered that there are bacteria and bacteria There are some species of bacteria which, when planted in a wound, will bring forth as the result of the poisonous materials formed by them, the formation of pus with the resulting septic fever, as certainly as the acorn when planted and nourished will develop into the sturdy oak There are other species which when they come in contact with a wound are practically harmless Of course we can not with the naked eye distinguish between the poisonous bacteria and the harmless ones, and hence our only safe plan is to as far as possible exclude them altogether from wounds, whether made by violence, or those made during surgical operations How, then, can this be done? The first point to be observed is, to use as little water or watery antiseptic solutions as possible in contact with the wounds made during surgical operations The reason for this course is that by so doing we remove one of the essential conditions necessary for the development of bacteria, and thus prevent or at least hinder their growth

It is practically impossible to diminish or prevent the growth of bacteria in a wound, by either raising or lowering the temperature of the wounded parts, hence we can only endeavor to accomplish this object by making use of the other two methods of limiting bacterial growth, viz to keep all wounded surfaces as dry as possible, and exclude them from the action of the atmospheric poisonous germs during the process of repair

Simple and self obvious as these principles of treatment may appear to be, yet they are largely neglected and ignored by very many surgical operators at this very time Often during an operation performed even by a most eminent surgeon (let us say an amputation), we see the field of operation deluged with a solution of boric acid, a solution of carbolic acid, or worse still a solution of mercuric chloride This seems to be radically wrong in practice and entirely inconsistent with the elementary principles of aseptic surgery Of course, in operations which require the opening or removal of large suppurating cysts or cavities, it is necessary to wash them out This should be done, we believe, with fluids as near the composition of blood serum as possible That wonderful operator, Lawson Tait of Birmingham, England, who has nearly completed his third thousand of operations upon the abdominal cavity, uses no fluid to wash out the abdominal cavity during his operations, excepting recently boiled water

For use in surgical operations the following fluids only are necessary, viz recently boiled water used tepid (about the temperature of 100 F) and normal salt solution (0 75 per 1000 easily made by dissolving one ounce, avordupois, of common salt in a gallon of boiling water)

Aseptic surgery therefore, after all is nothing but cleanliness, but when we say that, we mean cleanliness carried to a microscopic degree of perfection, and far surpassing the ordinary ablutions by soap and water What we endeavor to do at the present time, before any surgical operation is to so thoroughly cleanse the patient, the surgeons, assistants, nurses, surgical appliances and dressings (of course including the hospital and all its surroundings) so that no germs of poisonous bacteria can infect the wound, and cause suppurating fever, and perhaps the death of the patient operated upon Modern surgery starts out with the assumption that in an operation aseptically performed upon an aseptic patient, and by an aseptic operator, there should be neither suppuration nor fever following any surgical operation This of course is the ideal of surgery, which can not always be realized, but nevertheless it is the goal towards which we should aim, and which we should always endeavor to attain

Every instrument and surgical appliance must be sterilized shortly before the operation, either by boiling in water containing 1 per cent of carbonate of soda (commonly called washing soda) half an ounce to three pints of water, or by being exposed to a dry heat above the temperature of boiling water (from 230 to 240 degrees Fah) for one-half hour before the operation

This can be done in the various patterns of steam and dry sterilizers which are now on the market, and can be procured at a moderate cost But my principal object in writing this article is to call attention to the fact that aseptic surgery can be practically carried out without the purchase of any apparatus whatever A tin wash boiler, which can be found in the humblest home is just as good for sterilizing surgical instruments as Arnold's, or other of the steam sterilizers now in use A still more simple sterilizer for small instruments is the ordinary oblong tin baking pan, so familiar to our eyes in our youthful days This pan when filled with boiling solution of carbonate of soda, may not look quite so ornamental as a porcelain evaporating dish, or a forty dollar copper sterilizer, but it will do just as good work As before mentioned, to the above must be added absolute cleanliness of the operator, assistants, nurses, and in fact of all who come in contact with the patient It is scarcely necessary here to say that the part operated upon, and the arms of the operator, assistants and nurses must be thoroughly scrubbed first with soap and water, and then with solution of one to 2000 mercuric chlorid, just before the operation

One incidental and very great advantage in operating in private houses, providing they are clean and in good sanitary condition, is that the germs of poisonous bacteria are for obvious reasons not so liable to be found there as in the air of crowded hospitals In regard to the sterilization by the dry method, the only thing that is absolutely necessary to be purchased is a good thermometer, graduated to a temperature of 300 degrees Fah Of course it is convenient, and perhaps more surgical looking, to buy a dry sterilizing apparatus, but it is by no means essential The oven of a kitchen range or that of an ordinary cooking stove will answer every purpose Take a common pasteboard box, such as letter envelopes are packed in, place in the bottom of it a layer of aseptic cotton about two inches in thickness, lay on this your instruments and surgical appliances (bandages, etc.) with your thermometer, and your apparatus will then be complete. Place in the oven and expose to a temperature of 230 to 240 degrees Fah. This temperature can be easily regulated by a little practice, and is lower than the temperature required for ordinary baking purposes, which is said to be 270 degrees Fah. Finally, allow me to add the following maxims: 1. Never use a drainage tube in a wound unless you are absolutely certain you can get union by first intention. 2. If you have an amputation to perform, ligate every vessel requiring it with aseptic catgut, silkworm gut or silk; cut the ligatures off close to the vessels and leave them in the stump, close the flaps with similar sutures, and use no adhesive plasters in contact with the flaps of the stump. After you have stitched up the flaps, dust their surfaces with iodoform, boric acid, or subnitrate of bismuth. Place over this a layer of iodoform gauze, then an abundant layer of aseptic cotton, and over all this two layers at least of a well-fitting bandage. The reason why I do not use adhesive plaster in contact with the flaps of the stump, is that it can not be properly sterilized, and is very often the means of infecting the stump.

Above all things, never open a stump for ten or twelve or even fifteen days after an amputation, if the temperature of the patient is at normal point, or even a degree above. The last limb I amputated was dressed for the first time on the sixteenth day after the operation. On the other hand, if the temperature goes up to 102 or 103 degrees, open up the stump at once, and find out the cause of the trouble. In Bichât Hospital (located in Paris, France), I saw a number of stumps of amputation in the summer of 1892 which had only received two dressings, one on the fifteenth day, and the other final dressing on the twenty-eighth day after the operation.

ADDRESS

CHAIRMAN'S INTRODUCTORY ADDRESS.

Read before the Section on Ophthalmology, at the Forty-fourth Annual Meeting of the American Medical Association.

BY S. D. RISLEY, M.D.
PHILADELPHIA, PA.

I can not refrain from expressing my high appreciation of the honor you have conferred in calling me to preside over the deliberations of the section. Permit me to extend my most cordial greetings and to express the personal gratification I feel in again meeting my colleagues in ophthalmology from all sections of our country. It is fitting that I should congratulate the section that its members have again been spared through the toil and vicissitudes of a year and are still actively engaged and deeply interested in this beneficent work. The activity displayed everywhere as set forth in a rapidly growing special literature is encouraging, not to say inspiring. Not only are periodicals devoted to ophthalmology multiplying, but the character of the papers published are rapidly improving. Careful scientific work is obviously on the increase and the clinical papers also portray a class of work far superior to that of only ten years ago. To me this has been a source of great encouragement and to us all just cause for congratulation. There can be no question as to the large share the members of this section of the American Medical Association have had in this advance. It is my ambition to see it assume the rôle of authority in our special work in the United States, so that its utterances shall be regarded as the expression of the latest and best opinions. In uttering this sentiment I am sure that I but voice the feeling of every member of the section. If this ambition is to be realized, however, to any higher degree than in the past, it must be through the unselfish devotion of every member, not only in his everyday individual work in laboratory and library, clinic and consulting room, but devotion also to the interest of the section. While I have no doubt this feeling of devotion has been entertained by every member, our methods of section work have not afforded adequate means for its expression. The fault, if any, has been in a lack of careful organization. There has been no lack of material; indeed, we have been overwhelmed with the abundance presented for consideration and discussion, but we have been too prone to content ourselves with the simple recording of the facts of our experience. Paper after paper has been presented, manifesting the most painstaking and interesting observation of unusual experiences. Some discussion has followed or similar experiences have been doubtfully reported from memory, thus adding to the richness of material, but in the end much loss has been sustained, both from want of time for adequate discussion and from the want of classification of reported facts. I fear I shall take too much of your valuable time by attempting to present this in all its bearings, so content myself with the statement that our design should be, first of all the presentation of the carefully prepared papers, and for this the greatest latitude should be accorded. To adopt any method which would hamper this feature of our work would, I am sure, be a great mistake. But in order to secure the highest usefulness it would be of great service if each member should study the list of expected papers and prepare for the discussion by reviewing his own experience in the same direction. By this means we would secure a consensus of opinion and the section speak as a body in its transactions, instead of presenting simply collections of individual views as expressed in the published papers. In the second place, special provision should be made for the elaborate study of some special topic or some form of disease which has baffled our skill or about which there is diversity of views as to nature and treatment. For this purpose I would suggest that at each annual meeting a commission should be appointed for the investigation of some selected subject, to report at the following annual meeting. By way of illustration, who of us would not like to have the report of such a commission, e. g., hemorrhagic glaucoma or retro-bulbar neuritis, or the pathogenesis of the myopic eye, or the nuclear palsies of the ocular muscles, or the anomalies of ocular balance. Then a carefully organized discussion of the report of the commission would secure a valuable review of the subject and the consensus of opinion of the section, which would find place in special literature, be widely quoted and the reputation of the section and of American ophthalmology be greatly increased. Such studies would render the sessions of the section so valuable that none of us could afford to miss its annual meeting and thus the prosperity of the section would be generally enhanced In the publication of our special bound volume I would suggest that the discussion should also be included so that any unusual views presented by the author of a paper should stand in juxtaposition to the expressed views of his colleagues

PANNUS AND ITS TREATMENT BY THE DIGESTIVE FERMENTS

Read in the Section of Ophthalmology, at the Forty fourth Annual Meeting of the American Medical Association

BY JAS A LYDSTON, M D, Ph G

Formerly Professor of Inorganic and Medical Chemistry and Lecturer on Diseases of the Eye and Ear, Chicago College of Physicians and Surgeons, Chicago, Ill

The etiology and course of pannus are so fully appreciated that it will not be necessary to consume valuable time by entering into a lengthy description of the disease, suffice it to say for the purposes of my paper that inasmuch as pannus is one of the most frequent sequelæ of trachoma I shall limit my remarks to the so-called granular pannus, that is, that form in which the formation of granular masses in the corneal layers has caused infiltration and vascularity of the corneal surface

In this type, the morbid changes first begin to assert themselves in the upper margin of the cornea at the limbus conjunctivæ and we note further that its tendency to clear is in direct proportion to the degree and duration of the inflammatory process, in other words, the further the process departs from the character of a simple infiltration throughout the more ominous will be the prognosis and, indeed, in the light of our present knowledge bearing on this subject we know that complete reparation after pannus which implicates the deeper corneal layers is a forlorn hope, but in all cases in which the cell migration which constitutes the infiltration in pannus is confined to the corneal region lying between the anterior elastic lamina or Bowman's membrane and the corneal epithelium there is an intrinsic tendency to clear In proportion, however, to the increased aggregation of cells, Bowman's membrane undergoes atrophic changes and finally is obliterated, thus permitting the process to extend more deeply From a histological standpoint, pannus proves to be a layer of newly formed, soft, cellular tissue greatly simulating in appearance the infiltrated trachomatous conjunctiva This tissue is more or less vascular and occurs in more or less typical layers imparting an uneven nodular aspect to the growth Special terms have been assigned to the disease which are to a certain extent descriptive of pannus in the several types, thus we have pannus tenuis, which indicates a recent pannus exhibiting no great thickening, again, pannus vasculosus, signifies the vascular type, and pannus crassus or carnosus implies a very dense pannus, still further, we have pannus sarcomatosus, which is an unfortunate term, inasmuch as it generates confusion with neoplasms, finally, we have pannus siccus which is mostly composed of connective tissues, there being few or no blood vessels

In the management of this class of cases the preeminent notion heretofore has been to cure the conjunctival affection from which the disease takes its departure, it being held that the pannus will spontaneously disappear, with this object in view various therapeutical measures have been resorted, to such as are usually exhibited in the treatment of trachoma, for example, nitrate of silver in solution or substance, sulphate of copper in solution or in the form of "blue stick" as it is called, and the various antiseptic measures have all found fitting application, and even the more radical measure of inoculation, either with the pus of an acute blennorrhea as advised by Piringer and Jaeger, or the milder method of jequirity treatment first advocated by De Wecker In conjunction with the foregoing ponderous array from the therapeutical armamentarium the surgical procedures of syndectomy, iridectomy and sclerotomy, and even an attempt at radical removal of the growth by scraping as advised by Gruening have all been utilized in these cases, and notwithstanding the great mass of literature that has accumulated in the course of time, we are still far from a unity of views with respect to the treatment of pannus Within the last year I resorted to a mode of treatment which was particularly pleasing to me in its results and I herewith present an outline of the course adopted, not with any idea that it will wholly supplant the foregoing measures, but if it proves as efficient in the hands of others as in my own, that it may become an advantageous auxiliary in the management of such cases I refer to the treatment of pannus, particularly that type characteristic of trachoma by the digestive ferments The first case in which I employed a digestive ferment was in that of a man aged 45 who had suffered with trachoma and its ravages for a period of eight years Papillary hypertrophy and trachomatous granules were still quite noticeable, together with very perceptible atrophy of the conjunctiva tarsi and a very pronounced pannused condition of both corneæ, which rendered it impossible for the patient to get about unattended Entropion had also supervened Viewing pannus as a new growth more or less vascular in type, I surmised that if I could but bring a medicament in contact with it that possessed powerful digestive properties I could favor its removal, and with this object in view I resorted to daily inspersions of powdered papoid with boric acid Papoid is the new proteolytic agent derived from the carica papaya or papaw plant, and bids fair to become a most valuable addition to our materia medica This agent exhibits the power of digesting all types of proteid and albuminous substances, both in a coagulated and uncoagulated form, and its digestive properties are still further enhanced by the fact that it acts in acid, alkalin and neutral media, though, as my experience demonstrates, more pronounced in alkalin solution So true did this medicament maintain its digestive powers that the remaining trachomatous granules gradually disappeared, and the pannus began to thin perceptibly, finally, after a course of constant medication with the before mentioned medicament, extending over a period of three months, such a marked change had transpired that the patient was able to get about unattended, and with the application of suitable glasses can read ordinary newspaper type at the distance of twelve inches and Snellen's D-18 at eighteen feet When the process of clearing had reached its maximum degree the admirable operation designed by Dr Hotz was instituted for the removal of the entropion, and thus the lids were placed more nearly in normal apposition to the eyes, and the gentleman to-day rejoices in a very fair amount of vision in spite of many gloomy predictions to the contrary The second case was that of a woman aged 30, who was suffering with chronic granulations and a pannused state of both corneæ, though the pannus was not quite so dense as in the preceding case Here the same favorable results ensued, the granulations gradually absorbing, the hypertrophic papillæ disappearing and the pannus progressively diminishing in density until a fair amount of vision was restored to an individual who had abandoned all hope of ultimate recovery The granulations melted away like a piece of ice in full sunlight and apparently had no tendency to reappear A third case in which I applied the remedy is that of a woman aged 35 who had sustained a siege of trachoma affecting both eyes with consequent pannus of the vascular type, and in this case as in the preceding, a diminution of all the inflammatory symptoms ensued together with pronounced thinning of the pannus, and perceptible clearing of the corneæ with great improvement of vision, and I am convinced by the foregoing cases that we have in the digestive ferments, particularly papoid, a very efficient and safe digestant applicable in these cases

The argument will no doubt be advanced that it is not possible to digest living animal membrane to a degree sufficient to warrant the application of the remedy in such cases, but in opposition thereto, I hold that the new growth is necessarily of low vitality, depending as it does for its nutritive pabulum upon the conjunctival and embryonic vessels peculiar to itself, and is largely composed of lymphoid structures which have appeared to be particularly susceptible to the digestive influence of the ferment In order to demonstrate its powerful digestive qualities I immersed a densely leucomatous eye which had been blinded by smallpox and recently enucleated and present it herewith for your inspection You will notice that it is almost completely digested It is now one week since the eye was thus treated, the strength of the solution being 30 grains to the ounce, and indeed it had reached its present state of digestion on the second day of its immersion which indicates that papoid exhibits powerful digestive qualities when brought in contact with animal membrane, and certainly if it is capable of virtually digesting the cicatrized envelope of an eye, which as we know even in a normal condition is quite resistant to the action of chemical agents generally, its effect in this instance is strikingly suggestive, and leads to the conclusion that its digestive properties have not been over estimated In an article entitled, "Some Observations on the Clinical Uses of Papoid," by Dr Arch Dixon of Kentucky, he states that "he has used papoid with marked benefit in diphtheria, membranous croup and indolent ulcers, and as a solvent for dead bone" My own experience while still limited, leads me to confirm his conclusions when he says, "that papoid under papoid conditions produces greater results than pepsin under pepsin conditions" I have made application of pepsin, both in solution and in powdered form in cases of granular conjunctivitis associated with pannus, and have not reached the satisfactory results that I was able to obtain with papoid

Dr Taylor—In what proportion is papoid and boric acid used, and how often is the application made?

Dr Lydston—I apply the remedy twice a day in the treatment of pannus, the patient being willing to come to my office that often, otherwise I apply it only once a day I use equal parts of papoid and boric acid

Dr De Schweinitz—In what strength do you use the remedy, how do you apply it and what is the reaction?

Dr Lydston—I take equal parts of papoid and boric acid, after mixing them thoroughly I dust the mixture on the cornea by means of a camel's hair brush, only a slight reaction following

SELECTIONS

Pathological Models at the World's Fair

In order to draw attention to some of the exhibits from the Pathological Institute of Berlin University, now on exhibition at the World's Fair, we reprint herewith Dr Berliner's account of these from an article originally published in the *Deutsche Med Wochenschrift*

"Plastic Reproductions of Preparations from Pathological Anatomy, by Dr Paul Berliner, Berlin, Germany In any demonstrative science, clinical instruction is of the greatest importance, therefore every teacher of medicine, whenever possible, endeavors in his lectures to help his hearers to an easy comprehension of his subjects, either by exhibition of a patient, of pathological preparations and instruments, or corresponding illustrations of the same For this reason, also, medical literature contains abundant illustrations, for the production of which all forms of graphical methods are brought into use However, notwithstanding the perfection of photographical, chromographical and similar illustrations, medical science often presents to the student cases in which the mere physical aspect, or gross anatomy, is insufficient, and a plastic representation is necessary for a clear understanding thereof This is especially true when applying to dermatology, embryology, or normal and pathological anatomy If, therefore, from the plastic reproduction (or representation) the model is perfected by careful coloring copied from the original, it should certainly be the most complete way of permanently presenting those natural objects which are themselves rapidly perishable, and retaining the peculiarities of their changeable, or temporary appearances and conditions The combination of "polychromy" with plastic art makes it possible to produce objects wonderfully similar to the fresh, natural preparation

The idea of perfecting plastic preparations is not a new one (At first it was confined to only normal anatomy and later pathological anatomy) Preparations were formed out of various materials chiefly wax, and brought together in collections

In literature, only isolated notices are occasionally found of such collections, which I have gathered together as far as possible without attempting completeness

Hyrtl, in the preface to his "Anatomy of the Human Body," states that Emperor Joseph II, had presented to the school of military surgeons in Vienna (now extinct) the then world-renowned collection of anatomical wax preparations, equaled only by a similar one in Florence Both collections were made under Fontana's direction by the Italian artist Gaetano Zumbo, and the Spaniard "Novesis"

The anatomical museum in Vienna contains a few wax models made by Dr Dom Bastler, a practicing physician of that city in the earlier part of this century At the present time these anatomical wax preparations are made princinone of us could afford to miss its annual meeting and thus the prosperity of the section would be generally enhanced In the publication of our special bound volume I would suggest that the discussion should also be included so that any unusual views presented by the author of a paper should stand in juxtaposition to the expressed views of his colleagues

PANNUS AND ITS TREATMENT BY THE DIGESTIVE FERMENTS

Read in the Section of Ophthalmology, at the Forty fourth Annual Meeting of the American Medical Association

BY JAS A LYDSTON, M D , Ph G

Formerly Professor of Inorganic and Medical Chemistry and Lecturer on Diseases of the Eye and Ear, Chicago College of Physicians and Surgeons, Chicago, Ill

The etiology and course of pannus are so fully appreciated that it will not be necessary to consume valuable time by entering into a lengthy description of the disease, suffice it to say for the purposes of my paper that inasmuch as pannus is one of the most frequent sequelæ of trachoma I shall limit my remarks to the so-called granular pannus, that is, that form in which the formation of granular masses in the corneal layers has caused infiltration and vascularity of the corneal surface

In this type, the morbid changes first begin to assert themselves in the upper margin of the cornea at the limbus conjunctivæ and we note further that its tendency to clear is in direct proportion to the degree and duration of the inflammatory process, in other words, the further the process departs from the character of a simple infiltration throughout the more ominous will be the prognosis and, indeed, in the light of our present knowledge bearing on this subject we know that complete reparation after pannus which implicates the deeper corneal layers is a forlorn hope, but in all cases in which the cell migration which constitutes the infiltration in pannus is confined to the corneal region lying between the anterior elastic lamina or Bowman's membrane and the corneal epithelium there is an intrinsic tendency to clear In proportion, however, to the increased aggregation of cells, Bowman's membrane undergoes atrophic changes and finally is obliterated, thus permitting the process to extend more deeply From a histological standpoint, pannus proves to be a layer of newly formed, soft, cellular tissue greatly simulating in appearance the infiltrated trachomatous conjunctiva This tissue is more or less vascular and occurs in more or less typical layers imparting an uneven nodular aspect to the growth Special terms have been assigned to the disease which are to a certain extent descriptive of pannus in the several types, thus we have pannus tenuis, which indicates a recent pannus exhibiting no great thickening, again, pannus vasculosus, signifies the vascular type, and pannus crassus or carnosus implies a very dense pannus, still further, we have pannus sarcomatosus, which is an unfortunate term, inasmuch as it generates confusion with neoplasms, finally, we have pannus siccus which is mostly composed of connective tissues, there being few or no blood vessels

In the management of this class of cases the preeminent notion heretofore has been to cure the conjunctival affection from which the disease takes its departure, it being held that the pannus will spontaneously disappear, with this object in view various therapeutical measures have been resorted, to such as are usually exhibited in the treatment of trachoma, for example, nitrate of silver in solution or substance, sulphate of copper in solution or in the form of "blue stick" as it is called, and the various antiseptic measures have all found fitting application, and even the more radical measure of inoculation, either with the pus of an acute blennorrhea as advised by Piringer and Jaeger, or the milder method of jequirity treatment first advocated by De Wecker In conjunction with the foregoing ponderous array from the therapeutical armamentarium the surgical procedures of syndectomy, iridectomy and sclerotomy, and even an attempt at radical removal of the growth by scraping as advised by Gruening have all been utilized in these cases, and notwithstanding the great mass of literature that has accumulated in the course of time, we are still far from a unity of views with respect to the treatment of pannus Within the last year I resorted to a mode of treatment which was particularly pleasing to me in its results and I herewith present an outline of the course adopted, not with any idea that it will wholly supplant the foregoing measures, but if it proves as efficient in the hands of others as in my own, that it may become an advantageous auxiliary in the management of such cases I refer to the treatment of pannus, particularly that type characteristic of trachoma by the digestive ferments The first case in which I employed a digestive ferment was in that of a man aged 45 who had suffered with trachoma and its ravages for a period of eight years Papillary hypertrophy and trachomatous granules were still quite noticeable, together with very perceptible atrophy of the conjunctiva tarsi and a very pronounced pannused condition of both corneæ, which rendered it impossible for the patient to get about unattended Entropion had also supervened Viewing pannus as a new growth more or less vascular in type, I surmised that if I could but bring a medicament in contact with it that possessed powerful digestive properties I could favor its removal, and with this object in view I resorted to daily inspersions of powdered papoid with boric acid Papoid is the new proteolytic agent derived from the carica papaya or papaw plant, and bids fair to become a most valuable addition to our materia medica This agent exhibits the power of digesting all types of proteid and albuminous substances, both in a coagulated and uncoagulated form, and its digestive properties are still further enhanced by the fact that it acts in acid, alkalin and neutral media, though, as my experience demonstrates, more pronounced in alkalin solution So true did this medicament maintain its digestive powers that the remaining trachomatous granules gradually disappeared, and the pannus began to thin perceptibly, finally, after a course of constant medication with the before mentioned medicament, extending over a period of three months, such a marked change had transpired that the patient was able to get about unattended, and with the application of suitable glasses can read ordinary newspaper type at the distance of twelve inches and Snellen's D-18 at eighteen feet When the process of clearing had reached its maximum degree the admirable operation designed by Dr Hotz was instituted for the removal of the entropion, and thus the lids were placed more nearly in normal apposition to the eyes, and the gentleman to-day rejoices in a very fair amount of vision in spite of many gloomy predictions to the contrary The second case was that of a woman aged 30, who was suffering with chronic granulations and a pannused state of both corneæ, though the pannus was not quite so dense as in the preceding case Here the same favorable results ensued, the granulations gradually absorbing, the hypertrophic papillæ disappearing and the pannus progressively diminishing in density until a fair amount of vision was restored to an individual who had abandoned all hope of ultimate recovery The granulations melted away like a piece of ice in full sunlight and apparently had no tendency to reappear A third case in which I applied the remedy is that of a woman aged 35 who had sustained a siege of trachoma affecting both eyes with consequent pannus of the vascular type, and in this case as in the preceding, a diminution of all the inflammatory symptoms ensued together with pronounced thinning of the pannus, and perceptible clearing of the corneæ with great improvement of vision, and I am convinced by the foregoing cases that we have in the digestive ferments, particularly papoid, a very efficient and safe digestant applicable in these cases

SELECTIONS

Pathological Models at the World's Fair

In order to draw attention to some of the exhibits from the Pathological Institute of Berlin University, now on exhibition at the World's Fair, we reprint herewith Dr Berliner's account of these from an article originally published in the *Deutsche Med Wochenschrift*

"Plastic Reproductions of Preparations from Pathological Anatomy, by Dr Paul Berliner, Berlin, Germany In any demonstrative science, clinical instruction is of the greatest importance, therefore every teacher of medicine, whenever possible, endeavors in his lectures to help his hearers to an easy comprehension of his subjects, either by exhibition of a patient, of pathological preparations and instruments, or corresponding illustrations of the same For this reason, also, medical literature contains abundant illustrations, for the production of which all forms of graphical methods are brought into use However, notwithstanding the perfection of photographical, chromographical and similar illustrations, medical science often presents to the student cases in which the mere physical aspect, or gross anatomy, is insufficient, and a plastic representation is necessary for a clear understanding thereof This is especially true when applying to dermatology, embryology, or normal and pathological anatomy, If, therefore, from the plastic reproduction (or representation) the model is perfected by careful coloring copied from the original, it should certainly be the most complete way of permanently presenting those natural objects which are themselves rapidly perishable, and retaining the peculiarities of their changeable, or temporary appearances and conditions The combination of "polychromy" with plastic art makes it possible to produce objects wonderfully similar to the fresh, natural preparation

The idea of perfecting plastic preparations is not a new one (At first it was confined to only normal anatomy and later pathological anatomy) Preparations were formed out of various materials chiefly wax, and brought together in collections

In literature, only isolated notices are occasionally found of such collections, which I have gathered together as far as possible without attempting completeness

Hyrtl, in the preface to his "Anatomy of the Human Body," states that Emperor Joseph II, had presented to the school of military surgeons in Vienna (now extinct) the then world-renowned collection of anatomical wax preparations, equaled only by a similar one in Florence Both collections were made under Fontana's direction by the Italian artist Gaetano Zumbo, and the Spaniard "Novesis "

The anatomical museum in Vienna contains a few wax models made by Dr Dom Bastler, a practicing physician of that city in the earlier part of this century At the present time these anatomical wax preparations are made principally in Paris and Lille, from whence they are exported all over the continent Most of that class of models exhibited in Germany, particularly those of a pathological character, are of French origin Most famous in Paris is the Musè Baretta in the Hospital St Louis, as is also the syphilographic collection of "Jumelin "

Among other manufacturers should be mentioned "Tramond" of the medical faculty of Paris University He has published a voluminous catalogue of his preparations

The department of Pathological Anatomy of the Berlin Charité, possesses a collection of models which were made by Dr Felix Thibert of the Paris University

Prof Schuller, in a recently published account of his travels, states that most of the North American Universities also make use of wax models in their didactic and clinical lectures, and Prof Schuller informs me these have also been imported from Paris

In Germany, models of normal anatomy are manufactured in Munich and Dresden, and a Dr A Ziegler of Freiberg, furnishes preparations for the study of embryology

Herr Lassae of Berlin, has directed his attention to the plastic reproduction of skin diseases, and has laid the foundation for a large collection of dermatological wax models which are reproduced from material furnished by his clinics

As for myself, I at first made plastic preparations from only the skin clinics of the Breslau University, but soon made use of them in other departments of pathology, especially from diseases peculiar to the viscera I believe I can claim the right of priority in the introduction of the last named preparations My *intention* is to *introduce* this method of reproduction more generally by such preparations, and I believe it is deserving of more attention from the medical profession than has heretofore been accorded it The practical advantages of these preparations from whatever medical specialty they be taken, is that while in possession of these artificial reproductions one has always at hand an exact imitation as to size and coloring of the original, and can make use of them while teaching, either for demonstration or comparison with other preparations Herein lies also the advantage of this method of illustration over the use of the originals, which being preserved in fluids are subject to constant change in form and coloring Also the rapidly changing appearances on the living subject afford only a more or less unsatisfactory objective picture of the disease in question, and therefore with the model we possess a permanent reproduction or appearance of the different morbid conditions and are not obliged to depend on memory, or the individual conception of a single observer

There are important manifestations of certain diseases which the medical man during his student years finds no opportunity to become familiar with, perhaps because of the lack of clinical material or because during his course of clinical study these diseases were not prevalent at the time, but nevertheless diseases which every physician must be familiar with, as for instance the exanthema of typhus, etc In such cases a model perfectly true to nature may well serve for instruction and demonstration, in default of clinical material Among the various departments of medicine in which these plastic preparations are serviceable besides dermatology, is normal and pathological anatomy, and all the different newer methods of surgical operation, which can be well demonstrated on the plastic models Also certain conditions and appearances which are to be clinically observed on the patient resulting from the treatment in hand, can be permanently fixed and reproduced by this plastic method I have thus illustrated by these models in the skin clinics of the University of Breslau, the continuous manifestations of lupus affections which took place under the tuberculin treatment of Koch This should clearly demonstrate the value of these plastic preparations, for now that the above treatment has been abandoned, they offer for present and future consideration a vivid conception of those therapeutic measures which caused so much excitement in the medical world On the other hand, they will serve as objects for comparison and demonstration in case of renewal, improvement or adoption of another method of treatment

During epidemics, pathological changes in single organs, which differ according to the virulence of the poison, can be obtained and preserved in the same manner

These preparations are made by first taking a plaster cast of the subject to be reproduced This mold is then filled with wax made liquid in a water bath, and a positive is thus produced The model is then carefully painted with oil colors, true to nature Later, various varnishes are applied to give to it the moist appearance of the fresh or living tissue, and upon the correct imitation of which it depends

The most difficult part of the work is the correct coloring, and this is especially true in pathological more than in dermatological preparations In skin diseases the lesions are generally more scattered and better defined, while in pathological subjects the whole surface must be correctly reproduced in its natural coloring

Among the preparations exhibited by Dr Berliner are mentioned the following

1 Rectum, showing syphilitic changes of the mucous membrane Five cm from the anus a scar contraction On the anus itself, a large hemorrhoidal tumor Further, a rectal ulcer after cauterization with the Paquelin cautery showing where healing had commenced Slight edematous swelling and pigmentation of the mucous membrane The submucosa and muscular coats are plainly shown in the drawing

2 Kidney of new born infant, with uric acid infarcts (lues congenita)

3 Aorta—endarteritis deformans (with atheromatous degeneration) Chronic enlargement (or dilatation) of the aorta

4 Stomach with gastritis proliferans showing scattered spots or areas of hyperemia on the mucous membrane

5 Stomach with secondary carcinoma of mucous membrane (metastatic)

6 Liver—Chronic interstitial hepatitis, with jaundice (cirrhotic)

7 Lungs, with emphysema collapsed after opening chest cavity Broncho pneumonic hepatization in lower lobes

8 Lungs, showing active hyperemia

9 Section of lung with multiple cheesy deposits (pneumonic) Bronchial and peri bronchial inflammation

10 Section of lung showing recent pleurisy Excessive thickening of the pleura

11 Larynx with polypus on under half of right vocal cord

12 Larynx with syphilitic ulceration of the epiglottis

13 Larynx with tubercular changes

14 Puerperal uterus with septic infection

15 Thrombus of right femoral vein

NOTE —Nos 1 and 2 are at present in the possession of Herr G Lewin director of the skin clinic of the Royal Charité

Nos 11 12 and 13 are in the possession of Herr Prof Dr Fränkel, director of the clinic for throat diseases of Royal Charité Hospital

---

Memorandum of a Case of Hydatids of the Kidney, with some Remarks —By John B Hamilton, M D , LL D , Chicago, Ill Professor of principles of surgery and clinical surgery in Rush Medical College

In January, of this year, a young Dane came into my clinic as a patient, complaining of occasional attacks of renal colic On inquiry he stated that he had noticed after these attacks, certain white substances which his imperfect knowledge of English prevented him from describing I directed him to return when he was next attacked by colic, and enter the hospital

About the first of February he returned and I was enabled to see the substances passed with the urine, and I found them to be capsules of ecchinococci Careful examination was then made by abdominal palpation and the kidney was found enlarged to a considerable degree The patient's general condition did not seem to be affected, and his sole annoying symptom was the recurrent attacks of renal colic

Examination of the urinary deposit under the microscope showed the hooklets of the ecchinococci in limited numbers, and on February 4, 1893, at the Rush Medical College clinic, I cut down upon the kidney by lumbar incision made parallel with last rib The kidney was exposed and the perinephritic space packed with iodoform gauze, and an incision made directly through the kidney toward the pelvis The fluid contents of the cyst escaped through the wound, and daughter cysts round, white and shining, rolled out of the incision in great numbers Irrigation was then practiced, and the parent cyst having been entirely emptied of its contents was flushed with iodin water, and the wound was packed to the bottom with iodoform gauze The patient was comfortable after the operation, progressed toward a rapid convalescence and was well in four weeks

Although hydatids of the liver are comparatively common, those of the kidney are infrequent, and it is on account of this circumstance that I venture to present this brief case report There is now little dispute concerning the treatment of ecchinococci of the kidney, when a diagnosis is made, free incision is obviously the only correct procedure, but there is yet much to learn concerning the etiology and mechanism The dog, wolf and kangaroo have the general reputation of being the original host of these ecchinococci Their habitat is in the small intestine of those animals There is circumstantial evidence to corroborate this reputation in the fact that it is precisely in those countries where dogs and the animals named are more common that the ecchinococcus disease is most prevalent Iceland and Australia have the preeminence in frequency Cobbold states that in Iceland one-sixth of the mortality is caused by hydatid disease

Thomas published statistics of 7,156 cases of ecchinococcus disease observed in the hospitals of Australia He found 59 66 per cent located on the liver, 16 44 per cent located in the lungs, 2 55 per cent located in the epiploon and peritoneum, and 1 90 per cent located in the muscles Thomas, in 307 cases, found only two located in the kidney, but in Davaine it is stated that of 566 cases of ecchinococcus disease, thirty had their seat in the kidney One fact is noted in regard to hydatids of the kidney which seems to have no reasonable explanation, that is the greater frequency of the disease in the left than in the right kidney I am not prepared to offer even an hypothesis as to this fact which has been noted by all systematic writers on the subject

The allegation that the disease is more frequent in women than men might have an explanation in their greater fondness for pets, and the habit of kissing them

The statistics of ages of persons known to be affected by hydatid disease, vary from six years to sixty-five years, but the average is between twenty and thirty years

The practical lesson from these cases is that the disease is preventable, and appropriate hygienic measures should be adopted by those engaged in the slaughter of animals These measures consist in the care to be taken that no cystic tumors shall be allowed to go with the other offal, but be burned in a crematory, and by persons handling dogs that they do not kiss them, or allow the dog to lick the face My patient admitted that he had eaten raw meat, and kept several dogs, from either of which sources he might have obtained *the ova* of the cestoid —*Kansas City Medical Index*

Calomel as a Topical Application to Hemorrhoids —Dr J B James has written in favor of the above treatment, in *British Medical Journal* He states that he has for several years made use of calomel as a topical application to piles His success has been quite marked, especially in cases where inflammation has been produced in the abnormal tissues, characterized by mucous discharge and hemorrhage Under this simple treatment the annoying symptoms were generally soon relieved, and the patient absolved from the necessity of undergoing a perturbating course of treatment This method leads to the frequent ablution of the parts, and cleanliness is of itself curative in not a few instances The calomel is a cleanly kind of application, and commends itself to the patient for frequent and regular application It is readily applied and does not stain the clothing

SOCIETY NEWS

American Dermatological Association

Abstract of the Proceedings of the Seventeenth Annual Meeting, held in Milwaukee, Wisconsin, September 5 and 6, 1893

(Continued from page 506)

Dr E B Bronson of New York, followed with a paper entitled

THE TREATMENT OF PRURITUS

The author said in the management of *pruritus essentialis*, as of any other disease, the first consideration should be directed to what caused the trouble The adoption of measures tending to remove any accidental conditions or influences through which pruritus might be occasioned is important Such causes include, besides various local sources of irritation, certain remote or general diseases and furnish the *indicatio causalis* in its more limited sense This, however, states the scope of the problem only partially What is of more importance is to establish principles of treatment fitted to those more special and more essential causes that constitute the necessary conditions of the disease and whence we derive the *indicatio morbi* These causes are traced under etiology, and it is they which must afford the only intelligent basis for the therapeutics of pruritus

The chief underlying condition in pruritus is hyperæsthesia, whether in its common significance of an excessive irritability of the sensory nerves, or in the sense of an excess or engorgement of sensation The prime indications, then are to allay irritability and to divert or annul the excess of nervous excitement Measures to remove local excitants include first of all, such as directly tend to prevent scratching To admonish the patient to refrain from this is usually of little avail Restraint may be possible during waking hours, but at night, when the trouble is always at its worst, and especially during the state of somnolence midway between sleeping and waking, no power can prevent it It can only be avoided by first mitigating the lesion through the aid of anti-pruritics Sedatives when used internally are apt to be disappointing The degree of general sedation that is required to affect the nerves of the skin in so intense a disturbance as pruritus often is, affords a sufficient reason why this method of treatment is usually objectionable Further than this, the depressing and atonic after effect on the nervous system tends to exaggerate the general hyperesthesia which is already essentially an atonic condition, and thereby increases the tendency to itching Especially objectionable are most of the narcotics The bromids, on the other hand, are often indispensable and may be required in liberal doses It is important to avoid the enervating effects of loss of sleep, and for this purpose sulphonal or some other hypnotic is occasionally needed In connection with this, two internal remedies which have been recommended by Bulkley are worthy of mention, and they are cannabis indica and gelsemium The former is known to be a cutaneous anesthetic as well as an analgesic, and by virtue of the former quality should be useful in pruritus

Carbolic acid is the most reliable and most generally useful anti-pruritic which dermatologists possess, It was well named by Unna "the opium of the skin"

The following "anti-pruritic oil" has been much employed by the author for years, both in local and so called universal forms of the disease, with no more untoward results than now and then a trifling dermatitis, when through oversight the patient has been allowed to make the applications too frequently, or has continued them too long The formula is

℞ Carbolic acid, ʒi–ii
Liquor potass, ʒi
Ol lini, ℥i
Sig Shake before using

To correct the disagreeable odor of the linseed oil a drop or two of bergamot may be added Salicylic acid and salol though less energetic in their effects, act similarly to the carbolic acid Thymol is also an admirable anti-pruritic, but on account of its irritating effect can not be used when the skin is sensitive

The author then dwelt on sensory stimulants, substitutive irritants, alteratives of cutaneous nutrition, and motor depressants In pruritis hiemalis an all important measure of treatment is protection against cold The sole cause of winter pruritus, aside from a special predisposing hyperæsthesia, is lowered temperature

Dr Joseph Zeisler of Chicago, Illinois, read a paper entitled

ANGIOKERATOMA,

and reported the following case The patient was a German, and 53 years of age, butcher by occupation Had never had any severe illness, but had malaria once Present illness began somewhat gradually about four years ago with red spots and verrucæ on the skin of different parts of the body He was under medical treatment and says he improved for a time He states that some of the red spots gradually disappeared at times, but returned and new ones arose in different localities During all this period his general health had not suffered in the least No anorexia, headaches, nor any other complaint There is no pain or itching in the skin lesions Patches of vitiligo of large size are found on the front and sides of the abdomen and on the right side of the thorax Some small patches in right axilla Faint patches on right side of chest posteriorly and on the neck Large patches on the penis and scrotum and small ones on the inner surface of the thighs There are some old marks of tinea favus on the scalp Nævus-like spots and small tumors are scattered over the body as follows On posterior surface of right ear are two small warts, red in color and vascular, one on posterior aspect of left ear On the ulnar surfaces of both forearms, beginning over the olecranon, are found red nævus-like patches of irregular contour and smaller isolated ones in the form of small pedunculated tumors The patches vary in size from three or four inches in circumference to the size of a dime They are red in color, vascular and slightly raised above surface of surrounding skin On the right forearm are numerous small tumors varying in size from minute spots to some the size of a hazel-nut The larger ones are all pedunculated, firm and vascular On the left forearm they are fewer in number Considerable œdema in the right hand and fingers Only one or two small warts on the extensor surface On palmar surface there are some on every finger except the index, and none on the wrist and ball of the thumb One was removed and found to consist of an outer layer of thickened epidermis surrounding a very vascular center Microscopical examination was made by Dr Zeisler Some of these tumors sprang out from beneath the finger-nails On the left hand the verrucæ were not so numerous and inclined more to the small vascular variety with two exceptions Large irregular red patches were also found over each patella, and a few smaller ones irregularly scattered over anterior aspect of the legs and thighs, also a few smaller ones over the posterior aspect of thighs and one over the back of each ankle Two small peduculated warts were also found on the back of right leg, another with some of the red patches on the nates near the gluteal fold No patches or tumors were found on abdomen, thorax or upper part of arms

The author reported this unusual and interesting case to show that the clinical picture of the disease is evidently not yet quite complete, and hoped that new examples of the disease would arise which would throw more light on the pathology and etiology of the affection

Dr J A Fordyce of New York, read a paper entitled

A CONTRIBUTION TO THE PATHOLOGY OF ACNE VARIOLIFORMIS (HEBRA)

Dr Fordyce called attention to the case described by Dr Bronson and himself in 1891 under the title of "Acne Varioliformis of the Extremities," which was at that time shown to originate in or about the coil glands This was identical with cases since reported by Politzer, Dubreuilh and others under the name of hydradenitis, and should go on record as an example of that affection While clinically it presented many points of similarity to acne varioliformis (Hebra), its pathological anatomy was quite distinct

The writer had examined microscopically a number of papules and papulo-pustules from two typical cases of the latter disease, and was able to trace its beginning to an inflammation about the middle and upper portions of the hair follicles and their sebaceous glands, while the coil glands were shown to be outside the inflammatory area Enormous numbers of staphylococci were found in sections from one of the cases examined which readily stained with Kuhne's carbolic-methyline blue solution These organisms were especially numerous about the middle and deeper portions of the hair follicles and contained within the external and internal root-sheath, in the connective tissue about the coil glands and in the subcutaneous connective tissue In considering their number, distribution and presence in the diseased area before the epidermis was involved, the writer was disposed to consider them a direct influence in producing the lesions In a secondary infection they would scarcely be found at so early a period in the evolution o the papule

As a result of his investigations, Dr Fordyce concluded that acne varioliformis (Hebra) was an inflammation of the pilo sebaceous system, of microbic origin, leading to destruction of these organs, and that Bazin was correct in naming the disease acne pilaris

The members of the Association, at the close of Dr Fordyce's paper, participated in a general discussion on pityriasis rosea, and pemphigus

The following officers were elected President, Dr Robert B Morison of Baltimore, Md , Vice-president, Dr George T Jackson of New York, Secretary and Treasurer, Dr Charles W Allen of New York, Member-at-Large of the Council, Dr J A Fordyce of New York

On motion, the Association adjourned to meet in Washington, D C , in May, 1894

The Missouri Valley Medical Society, at its meeting held in Council Bluffs, Iowa, Sept 22, elected the following officers

President, Dr A F Jonas of Omaha, first vice president, Dr A L Wright, of Carroll, Ia , second vice president, Dr Daniel Morton of St Joseph, Mo , treasurer, Dr T B Lacy of Council Bluffs, secretary, Dr F S Thomas of Council Bluffs The next meeting place will be at Omaha

The Cedar Valley Medical Society —The annual meeting of the Cedar Valley Medical Society will be held in Dubuque, Iowa, Tuesday, October 10 Papers will be read by the following Drs J W Jaggard, Chicago, Ill , J S Lewis, Dubuque, G F McDowell, Clear Lake, W Woodbridge, Central City, E C Dudley, Chicago, A R Brackett, Nashua, E Hornibrook, Cherokee, C L Whitmire, Waverly, H C Jungblutt, Sumner

The meeting will be followed by a luncheon Dr I S Bigelow is president of the Society and Dr W B Small, of Waterloo, is secretary

The Southern Surgical and Gynecological Association will meet in New Orleans on the 14th, 15th and 16th days of November The medical profession are cordially invited to attend Dr Bedford Brown of Virginia is president, and Dr W E B Davis of Birmingham Ala , secretary

---

ASSOCIATION NEWS

We clip the following from our valued and always welcome contemporary, the *Occidental Medical Times*

Oregon and the Association —Dr Plummer informs us that a member of the Association from Oregon writes to say that he wishes to present the different sections with a souvenir of their visit to the Pacific coast that shall be typical of the State of Oregon This incident indicates the interest in the Association that is being rapidly developed, and augurs well for the success of the meeting

The San Francisco County Medical Society —At the last meeting of the San Francisco County Medical Society, Dr C G Kenyon, the President of the State Society, brought up the subject of the meeting of the Association in '94, After some discussion the Society appointed a committee to cooperate with the Committee of Arrangements of the Association

Coming to California —Dr H Bert Ellis of Los Angeles the Assistant Secretary of the Association, informs us that he is already constantly in the receipt of letters from members of the Association who are preparing to attend the meeting He says that several of his correspondents want to come on in advance and stay all winter—we presume in Los Angeles

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE.
PER ANNUM, IN ADVANCE $5.00
SINGLE COPIES . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE., CHICAGO, ILLINOIS.
All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

SATURDAY, OCTOBER 7, 1893.

THE PLACE OF ERGOT IN OBSTETRIC PRACTICE.

There is probably no therapeutic application of a drug so constantly carried out as the administration of ergot in obstetrics, and yet this being the case there is no doubt that in many instances it is wrongly administered because it is not needed, because it will do harm and finally because it is given at such a time that uterine contraction is voluntarily or artificially produced by other means before the ergot is absorbed, and so it exerts its action long after the object of the physician has been accomplished. On the other hand, as pointed out by BOHN in the JOURNAL of Sept. 23, 1893, there are very good reasons for this routine practice. It is positively certain that postpartum hemorrhage can almost always be avoided, even in feeble patients by its use, and in cases where there is no trained nurse in attendance and the doctor can not remain for some hours near his patient it must be given, without exception, if the safety of the case is to be assured and the physician is to have his mind at rest. In the discussion of the paper it will be remembered that DUFF expressed doubts as to the harmlessness of the routine use of ergot, as he had already done in a paper in the *Therapeutic Gazette*, in which he asserted that ergot was apt, by producing contractions of the uterine muscle at the cervix, to lock up dèbris which might when imprisoned produce septic trouble. Practically, however, we do not believe that such an accident is liable to occur. On the other hand, it is undoubtedly a fact that the contraction of the uterine walls produced by ergot, drives out of its cavity blood and other materials, and finally it is certain that these substances are more septic in themselves and are not readily changed to a septic state, unless the obstetrician has passed his hand or instruments into the cavity of the uterus and so infected them.

The rule which should govern the use of ergot in labor is hard to define. As with all rules governing the use of drugs, its application depends more upon the judgment of the physician than upon a written law. *Ergot must not be used too early lest the child and mother be injured*, neither must it be used too late. As it takes almost an hour for the dose to be absorbed, when given by the mouth, the influence of the drug on the uterus can not be felt for that period, and there is therefore no danger in giving the drug as soon as the physician is certain that labor will be over, at least so far as the truth of the head is concerned, in half to one hour. We therefore believe *that ergot is to be used in almost every case where* the physician can not be at hand the instant hemorrhage or uterine relaxation is threatened, and that the practice so generally followed is productive of an amount of good which far outweighs the few instances in which it may not produce the best of results.

PROPHYLAXIS OF CHOLERA—RAPID DISINFECTION.

At the session of the Academy of Medicine of Paris on the 19th of September, M. LE FORT presiding, M. BROUARDEL invited attention to the fact that at the preceding session M. BABES had read a memorial showing that in 1890 Roumania, contrary to other countries of Europe, had escaped the cholera epidemic, thanks to quarantines which, following the ancient system had been applied in all their rigor. This rigor had been such that they had not hesitated to shoot two persons who had tried to force the land quarantine. On the contrary, in 1893 when the quarantine had not been applied, Roumania had been invaded by cholera in the same measure as the neighboring countries. From this M. BABES has leaped to the *conclusion that the Dresden* conference had in suppressing land quarantines adopted a fatal measure. "It is not doubtful," said M. BROUARDEL, "that the suppression of quarantines, pure and simple, without replacing them by similar measures, more simple than the former, in effect exposes Europe to the cholera infection, but such is not the result of following the conference of Dresden."

In the presence of the great inconveniences of the quarantines, which permitted disinfection by aeration and, above all by time, it was asked if it were not possible to obtain the same result by means of rapid disinfection. It is easy to see that the existing measures adopted by the powers represented at Dresden, are precisely those which were the objects of the conference as indicated in the question proposed. These measures were pointed out to be such as disinfection by sterilizers, isolation of the sick, traveling card to be carried by well persons, etc. These statements of M. BROUARDEL are reassuring, for they show that inspection is not proposed to be abandoned by the French, but only simplified and hastened

EDUCATIONAL MODELS

We print elsewhere a report by Dr Berliner on the method of preparation of models which will be read with interest for, although originally printed a twelvemonth ago, the bringing of some of them to America as part of the German educational exhibit at the World s Fair, makes the description fresh and entertaining

Teaching is but dry work without models or demonstrations, and one might as well undertake to teach practical anatomy by book, as pathology without diagrams and illustrations, as well also might the student learn the art of opera dancing by nightly observation of the ballet, as to learn the delicate handling of the scalpel without long practice on the cadaver Our students require more practical training than ever, for it is not less true now than in the days of King Agesilaus, whose answer, when asked what a boy should learn, was, "that which they ought to do when they become men" Medical colleges have been rather slow in the adoption of the educational methods in use in other branches of learning, but they now seem pressing forward in the right direction and, as in agriculture, certain preparation of the soil must precede the planting, so the object lessons of the schoolroom prepare the mind of the student for the technical models of the medical school, and for the severer test questions of daily life, when school days are long past

THE SANITARY MODE OF OATH ADMINISTRATION IN THE COURTS

The *London Lancet* and the *Sanitary Record* have been foremost in counseling abandonment of the "kissing of the book" by witnesses in the courts of justice It is practically an act of injustice, oftentimes, this long standing custom of bringing together, through the medium of the book, face to face and mouth to mouth, the cleanly and healthy, the uncleanly and infected A physician of London has recently been the subject of considerable public comment for declining, on sanitary grounds, to take the book oath The following is a condensed account of the recent occurrence taken from the *Pall Mall Gazette*

> "'Kissing the book' is likely before long to become one of the lost arts Another objector to the practice has turned up in the West London Police Court in the person of Dr Morris Wallace, called to give evidence in a case where one woman was charged with stabbing another in the eye with a fork The doctor said he had no religious scruples, but he considered that there was a risk to health involved in putting to his lips a book which had already been kissed by other people The magistrate suggested as a compromise kissing the inside of the volume But here, too, the doctor objected 'on sanitary grounds,' and he was finally sworn by holding up the right hand"

This may be the beginning of a "reform movement," and if so, it is only natural to see a medical man stepping to the front Not a few of our medical acquaintance habitually adopt the oath by affirmation, instead of the traditional method, in regard to which, it is no slander to remark that it is more honored in the breach than in the observance

MEDICAL EDUCATION

The Illinois State Board of Health at its last meeting, decided to resume the publication of the reports on medical education For the last two years, owing to various causes, none have been printed Dr J Collins Warren, President of the Section of Pedagogy of the Pan-American Medical Congress, in his address, after reviewing the subject in this country, says

"The reports on medical education by the Illinois Board, I do not hesitate to say have exerted a more powerful influence on the movement in education than any other publication which our medical literature has produced"

This is undoubtedly true These reports were object lessons to the profession and to the schools, and presented truthfully the status of the colleges Dr F W Reilly is now engaged in preparing the forthcoming report He is eminently qualified for the task, having assisted in the preparation of nearly all the reports that were issued by the Board

CHICKEN POX OR SMALLPOX

The death of Dr Thomas Richards at North Brothers' Island of smallpox is very sad It may be said to be the result of mistaken diagnosis, and carelessness upon his part in not being properly protected by vaccination He contracted the disease from a case of supposed chicken pox that was brought before the Vanderbilt clinique, which afterward proved to be smallpox

This is not the first time that a mishap of this character has occurred It is simply impossible always in the early stages to differentiate these diseases The man who says he can always diagnose a mild case of smallpox or varioloid has only encountered typical cases, or has had but a limited experience Experience has taught that the only safe way is to treat such cases as suspects, and wait for development Bringing uncertain cases of this character before classes during a clinique is unsafe, so long as all unexposed persons are unprotected by vaccination

French Sanitary Commissioner at Constantinople—Pursuant to a request from of the Ottoman Government M Chartemesse has been sent by the French Government to preside at the inauguration of the measures of combating the cholera which has been active in that city—*Bulletin Medical*, Sept 20

RUPTURE OF SMALL INTESTINE—LAPAROTOMY—ONE DEATH, TWO RECOVERIES

BY H C DALTON, M D
ST LOUIS
Professor Abdominal and Clinical Surgery, Marion Sims College of Medicine late Superintendent St Louis City Hospital

Rupture of the intestines is so rare that I am sure the report of the following cases will prove of sufficient interest to the Association to justify me in taking up a few moments of your time The cases particularly emphasize the urgent need of early interference in such injuries, if we would save our patients from rapid peritonitis and death

CASE I —RUPTURE OF JEJUNUM AND MESENTERY—LAPAROTOMY—DEATH

J W , æt 22 , laborer , entered the City Hospital in October, 1893 Twenty hours before admission, while stealing a ride on a freight train in Illinois, he fell from the top of the car striking his belly against the handrail in the descent He was brought to the hospital at 1 P M next day His temperature at that time was 103 F Pulse 120 F Percussion gave dullness in the dorsal gutters, and resonance anteriorly He was at once prepared for laparotomy Dr H H Mudd, who was holding a clinic at the time, kindly assisted me in the operation After thorough antiseptic precautions a median incision eight inches long, was made The cavity was found full of clotted and fluid blood The necessary handling of the intestine caused fresh bleeding which was at first thought to come from the liver, but a careful search revealed a complete transverse laceration of the jejunum at its spinal attachment, the end of the gut being separated to the extent of an inch or more The mucous membrane was greatly everted The tear extended an inch into the mesentery and owing to the depth of the rupture it was manipulated with great difficulty The mesentery was closed on both sides with interrupted iron dyed silk sutures An ordinary cambric needle two inches in length was used The upper end of the gut was inserted into the lower and the serous surfaces brought together by the interrupted Lembert suture, a large number being required The blood was washed from the cavity and the surgical wound closed Drainage was not used The patient never rallied from the shock, and died a few hours after the operation I can but believe that this patient would have recovered had he been brought to the hospital the day before The intestine was quite red though not adherent, peritonitis not having advanced sufficiently far to produce that effect

CASE II —RUPTURE OF JEJUNUM—LAPAROTOMY—RECOVERY

John I , æt 17, hostler, entered the City Hospital at 9 A M Feb 8, 1892, a half hour after being thrown from a horse The horse also fell and rolled over on the boy, boring the horn of the saddle into his belly A scalp wound four inches in length was found three inches above the left ear from which a considerable quantity of blood had escaped, sufficient to thoroughly saturate the patient's clothes Although the patient admitted shortly after admission that he was suffering considerable pain in the abdomen, he afterwards denied it, referring all the pain to the scalp wound I learned later that a patient in an adjoining bed had warned him that if he admitted having pain in the belly the doctors would "cut him open " Five or six hours after admission he reluctantly gave me the above history Careful inspection of the abdominal surface failed to show the least bruise or abrasion, but deep pressure gave pain in the umbilical region, and percussion gave dullness over the left side of the belly There had been considerable vomiting His pulse was now 105 F , temperature 101 8 F

The scalp wound had been cleaned and closed shortly after his entrance into the hospital After thorough antiseptic precautions a medial incision five inches long was made The small intestine was found collapsed This was followed to the upper portion of the jejunum where a transverse rupture an inch and a quarter in length was found Considerable blood and fecal matter was found in the left dorsal gutter This was washed out with warm physiological salt solution The wound in the gut was closed by interrupted iron dyed silk Lembert suture A glass drainage tube, surrounded by iodoform gauze, was placed in the pelvic cavity and the belly closed The tube was cleaned every hour for twelve hours Then at increased intervals for four hours, after which it was removed

The patient rallied nicely His temperature for four days varied between 100 F and 101 F , after which recovery was rapid

At the time of the removal of the tube, an accident occurred which had happened in several of my previous cases, i e , portions of the omentum had become strongly attached to the openings in the tube I found it impossible to detach the omentum until I had excised the invaginated portion The fistulous track left by the tube was filled with iodoform gauze, and a snug dressing applied The patient was discharged well March 20, twelve days after admission

CASE III —RUPTURE OF ILEUM—LAPAROTOMY—RECOVERY

Peter M , æt 20, was admitted into the hospital at 4 P M , Nov 20, 1891 Three hours prior to admission, while feeding a circular saw a piece of wood became detached, and with great force was thrown against his abdomen In a few minutes he grew faint and was compelled to lie down Vomiting soon developed, and pain became intense When admitted to the hospital he was in great pain paroxysmal in character Shortly after this he again vomited His pulse was 116 F and weak , hands and feet cold The face wore an anxious expression The respiration was hurried and superficial Examination of the belly showed a very slight abrasion four inches in length, extending from right anterior superior spinous process to umbilicus Percussion over this region gave a tympanitic note There was also some swelling at this site, as well as great tenderness and pain on pressure The urine was drawn and found normal, indicating an intact bladder His rectal temperature was 105 F

At 7 30 P M , three and one-half hours after admission, I opened the belly Prior to doing this, however, I had in the presence of Drs French and L I Mathews (who were visiting me at the time), made the diagnosis of ruptured intestine An incision four inches long was made in the right linea semilunaris which bisected the abraded portion about its middle Upon drawing out the ileum a transverse rupture about an inch long was found This was closed by five or six interrupted Lembert iron dyed sutures The omentum was also stitched to the wound A small quantity of fecal matter and a large quantity of peritoneal secretion was sponged from the cavity, after which it was closed without drainage, save a small piece of gauze which was left in the lower angle of the wound This was removed on the second day with great difficulty owing to the firm adhesion of the gauze Peritonitis had not developed

There was some contusion and hematoma in the adjoining mesentery The cavity was not irrigated, but the intestinal coils, while out of the belly, were washed with the salt solution As in the preceding case, the small intestine below the rupture was collapsed (This condition is almost always present in such cases as well as in intestinal obstruction)

(An interesting feature of this case was that a Meckel's diverticulum was found a short distance below the rupture It was an inch in length and about the same in width) The wound healed by first intention and the patient's recovery was rapid and uninterrupted Flatus and feces passed for the first time on the second day

I attribute the success in the last two cases to the early operation I believe, in the hands of a careful surgeon, almost all such cases can be saved Of course the main point is to make a correct diagnosis The symptoms following the injuries to the abdominal viscera are usually sufficiently plain I lay most stress upon the character of the pain It is usually intense and paroxysmal in character It is nearly always accompanied by vomiting

Blows upon the abdominal wall, unaccompanied by rupture of the viscera rarely give rise to such grave symptoms Usually a soothing application and rest will give relief If in spite of this simple treatment severe paroxysmal pain continues for some hours we may be sure, almost beyond doubt, that we have to deal with a grave condition for which laparotomy affords the only relief

Should the injury cause internal hemorrhage, percussion of the dorsal gutters will give dullness and thus make the diagnosis more certain Many such cases are lost by the so-called conservative surgeon waiting for symptoms of peritonitis Symptoms of peritonitis mean peritonitis and the operation is then in the vast majority of cases, followed by the usual result—death

After such injuries the patient should be carefully watched for a few hours, and a few hours only For my part I would rather make a mistake and operate immediately than to fail to operate in a single appropriate case For in the inappropriate cases, a simple exploratory operation would rarely result in death, and would add but little to the gravity of the case, while delay in appropriate cases would almost certainly result in death

I do not deny that blows on the abdomen may give rise to the described grave symptoms without visceral injury, but I do emphatically deny that such symptoms will continue for hours after the injury I am also not unmindful of the fact that in grave visceral injuries patients have recovered without surgical interference, but I desire to ask the procrastinating surgeon how many he thinks would recover without such aid,—how many such cases he has seen? Should he tell of such cases I would be glad to ask him if he was sure his diagnosis was correct, and to give us the reason for his faith

Cases of rupture of the liver and spleen are very much more liable to recover without surgical aid than rupture of the intestine or bladder In cases of the former kind, (i e, of the liver and spleen) unaccompanied by evidences of hemorrhage, an operation might be delayed many hours In such cases the surgeon should not hesitate to operate as soon as he is well satisfied that the expectant plan will fail, and this means that he should do it before the development of peritonitis

---

NECROLOGY

Dr Clarke of San Francisco, died Sept 14, 1893

Dr George G Shively of Waynesboro, died Sept 20, 1893

Dr J E Roche of Chicago, died Sept 29, 1893 The doctor's life was lost by an accident His horse ran away and the vehicle upset, throwing him into the river His body was not recovered for several days

Dr Walter Vought of New York City, died of typhoid fever September 24 He was a native of Buffalo, N Y, and educated at Yale College, Columbia University, at Heidelberg and Vienna He made nervous diseases the subject of special study, and was chief of clinic in that branch at the Vanderbilt Clinic He was a member of the New York Academy of Medicine, Pathological and other scientific societies In the summer of 1892, his name became a household word by reason of his having been appointed to the charge of the Fire Island station for cholera suspects He was 31 years old at the time of his decease

BOOK NOTICES

A Dictionary of Medical Science—Containing a full explanation of the various subjects and terms of anatomy, physiology, medical chemistry, pharmacy, pharmacology, therapeutics, medicine, hygiene, dietetics, pathology, surgery, bacteriology, ophthalmology, otology, laryngology, dermatology, gynecology, obstetrics, pediatrics, medical jurisprudence and dentistry, etc, etc By Robley Dunglison, M D LL D, late Professor of Institutes of Medicine in the Jefferson Medical College of Philadelphia Edited by Richard J Dunglison, A M, M D New (21st) edition, thoroughly revised, greatly enlarged and improved, with the pronunciation, accentuation and derivation of the terms In one imperial octavo volume of 1,181 pages Cloth, $7 00, leather, $8 00 Philadelphia Lea Brothers & Co, 1893

In a recent issue we announced the early publication of the new edition of this great work and favorite American dictionary

It now lies upon our table, and in examining it we are pleased to note, that all the old features that have made Dunglison's Dictionary so popular in the past have been retained Many new improvements have been made, to bring the work up to date No previous edition has witnessed so many additions and changes, in which the editor has apparently been greatly aided by the many dictionaries that have appeared since the last edition was issued

A perusal of the book will convince any one, that the "Dunglison" will still retain its well earned place in the medical library for a long time to come, as a monument to American scholarship

Bellevue Hospital and Its Internes—A presentation copy of this interesting book, "An Account of Bellevue Hospital, with a Catalogue of the Medical and Surgical Staff from 1736 to 1894," is before us It is from the De Vinne press, and faultless in its typographical dress It is abundantly illustrated, and attractive beyond anything of a medico-historical nature that has hitherto fallen under our notice About one-fourth of its letter-press is given up to the history of the hospital and about three-fourths are needed for the catalogue The latter part is that which must necessarily have entailed the laborious efforts of the editor Dr Robert J Carlisle, to gather together the records of a thousand or more names of practitioners who have gone forth from Bellevue's wards to the four corners of the earth Dr Carlisle has done his work patiently and fully, and he is to be congratulated if he has survived his labors and has his health A number of good portraits adorn the book, among the best of which are the faces of the late Drs Alonzo Clark and Henry B Sands The book is published under the auspices of the Society of the Alumni of the Hospital which may be addressed at No 5, West Fifty-eighth Street, New York City

Alabama State Medical Association—Transactions for 1893. The transactions of this Association appears in its usual well written form, contains some excellent papers but, above all, shows the most careful organization of probably any State society in the United States The report of the board of censors, annually published by this Association is unique It includes the reports of the examinations made by each county board of censors of candidates for admission to practice, with the comment of the censors thereon, a roll of county societies, the annual oration and various interesting papers The book is highly creditable to the Association and the publication committee The secretary is Dr Jas R Jordan of Montgomery, Ala

New York State Medical Association—Transactions for 1892 By all odds the most complete and comprehensive transactions that have reached our table thus far, are the transactions of this Association, comprised in a handsome volume of 834 pages It has been carefully edited for the Association by Dr O C Ludlow of New York The papers include the following "President's Annual Address," by Dr Judson B Andrews of Erie County "Pneumotomy for Relief of Tubercular Abscess and Gangrene of the Lung, Twice on the Same Patient," by Dr John Blake White of New York County "Traumatic Osteo-Arthritic Lesions which Involve the Proximal Segment of the Ankle Joint, Their Pathological Anatomy and Treatment," by Dr Thomas H Manley of New York County "Muscular Traction for Hip Joint Disease," by Dr Thomas M Ludlow Chrystie of New York County "Some Recent Cases of Appendicitis," by Dr Nathan Jacobson of Onondaga County "Ectopic Pregnancy," by Dr Henry D Ingraham of Erie County "Antiseptic Vaginal and Intra-Uterine Injections Unnecessary, if not Injurious, in the Daily Practice of Obstetrics," by Dr Darwin Colvin of Wayne County "The Palliative Treatment of Such Cases of Cancer of the Uterus and Its Adnexa as are not Amenable to Radical Operative Measures," by Dr J E Janvrin of New York County "A Case of Puerperal Eclampsia at the Seventh Month, With a Few Thoughts from Practical Experience as to Treatment," by Dr Douglas Ayres of Montgomery County "Tumors of the Orbit A Detailed Account of Nineteen Cases Illustrating the Paper on the Same Subject Presented to the New York State Medical Association at Its Meeting in 1891," by Dr Charles Stedman Bull of New York County "Paraplegia," by Dr Charles W Brown of Washington, D C "The Question of Maternal Impressions," by Dr H S Williams of New York County "Clinical Contributions to the Subject of Brain Surgery," by Dr Roswell Park of Erie County "A Plea for the Early Extirpation of Tumors," by Dr John W S Gouley of New York County "Remarks on a New Method of Intestinal Anastomosis," by Dr Benjamin M Ricketts of Cincinnati, Ohio "A Report of Some Cases of Compound Depressed Fracture of the Skull," by George D Kahlo of Indiana "The Achievements of American Surgery," by Dr Frederic S Dennis of New York County "Memoranda, Practical and Suggestive," by Dr H D Didama of Onondaga County "Acute Pleurisy," by Dr Frank S Parsons of Northampton, Mass "A Clinico-Pathological Study of Injuries of the Head, With Special Reference to Lesions of the Brain Substance," by Dr Charles Phelps of New York County " The Etiology of Gastric Ulcer," by Dr Charles G Stockton of Erie County "The Examination and Commitment of the Public Insane in New York City," by Dr Matthew D Field of New York County "Mitral Stenosis in Pregnancy," by Dr Zera J Lusk of Wyoming County "The Use of Electricity in Midwifery," by Dr Ogden C Ludlow of New York County "The Rôle of Microbes in Disease," by Dr N B Sizer of Kings County Abdominal Hysterectomy for Myoma," by Dr Frederick A Baldwin of New York County 'Extraction of Steel from the Interior of the Eye with the Electro Magnet," by Dr Alvin A Hubbell of Erie County 'The Mental Symptoms of Fatigue," by Dr Edward Cowels of Somerville, Mass "A Review of Some Injuries of the Upper Extremity," by Dr E M Moore of Monroe County "Fractures of the Patella Treated by Continuous Extension, Patients not Confined to Bed" by Dr Josehh D Bryant of New York County 'Winter Cholera in Poughkeepsie," by Dr James G Porteous of Dutchess County 'Suggestions Relating to Improvement of Quarantine," by Dr Stephen Smith of New York County "The Limit of Responsibility in the Insane," by Dr John Shrady of New York County "Some Personal Observations and Reflections upon Alcoholism, the Effects of Alcoholic Abuse upon Posterity, and the Treatment of Alcoholism" by Dr H Ernst Schmid of Westchester County "Climatology in Its Relation to Disease," by Dr S J Murray of New York County "Pelvic Version," by T J McGillicuddy of New York County "Should We Treat Fever," by Dr S T Armstrong of New York County "Brief Comments on Materia Medica, Pharmacy and Therapeutics of the Year Ending November 1, 1892," by Dr E H Squibb of Kings County "Dermic and Hypodermic Therapeutics," by Dr S. F Rogers of Rensselaer County "Some Recent Experience in Renal Surgery, by Dr E D Ferguson of Rensselaer County "The Treatment of Neglected Cases of Rotary Lateral Curvature of the Spine," by Dr Reginald H Sayre of New York County

The Necrology Record includes memoirs of the following deceased Fellows Drs Abram Du Bois, M Calvin West, Myron N Babcock, Lucien Damainville, Nathaniel Clark Husted, James Ferguson and William Chace

The Association is to be congratulated on this magnificent volume It is apparent to the most superficial observer that the organization of the Association nine years ago by those who adhere to the regulations of the American Medical Association have well performed their part E D Ferguson, M D of Troy, N Y is the secretary

Pennsylvania State Medical Society—Transactions for 1893. The transactions of this Society are comprised in a handsome volume of 288 pages, containing the minutes, the annual oration and the papers read at the meeting The volume contains papers by such well known authorities as Price, Shoemaker, Roberts, Tyson, Dixon and Mills Several of the papers are handsomely illustrated, and the book is well printed Wm B Atkinson, M D of Philadelphia is secretary

DOMESTIC CORRESPONDENCE

Antisepsis as She is Taught

Cleanliness is next to godliness

To the Editor—Some of the requirements of modern antisepsis, "such as shaving the pubes, sealing vagina and anus, and banishing paterfamilias, ante partum" must impress the veteran obstetrician much as the swallow tail coat and standing collar did an untutored savage in process of civilization Delighted and tractable he was until he came to put on these articles of apparel, when suddenly disrobing he resumed his war paint and feathers and with a "whoop" disappeared in the bush C M Fenn, M D

San Diego, Sept 18, 1893

MISCELLANY

The Health of the British Army—The report of the British Army Medical Department for the year 1891 has recently been issued The delay in its appearance is allowable when it is considered that reports have to come in from all parts of the world before the consolidation in the office of the director general can be made In turning over its pages the tabulated statistics naturally attract our attention first, and we are gratified to find that in the presentation of our own army medical statistics our military brethren are in no ways behind those of her Majesty's service We observe that the latter purport to give the rating of sickness under certain specified conditions of disease for the year and the average ratios for the previous ten years, but as a matter of fact the average ratios are given only for the years 1886-90, and a note at the bottom of each page of the tabulations announces that "the average ratios for ten years will be given in future years The average ratios for the six years, 1886 to 1891, will be given in the report for 1892, those for the seven years, 1886 to 1892, in that for 1893, etc" The reports of the surgeon general of the United States army for several years back have given the ratios for the preceding decade that the value of the ratios for the year reported may be appreciated the more readily. Again, the tables of the United States reports give the data for a larger number of specified diseases than are found in that now before us By way of illustration, the latter furnishes us with the rates for diseases of the respiratory system in gross, while the former specifies the rates of catarrhs and common colds, bronchitis, pneumonia, pulmonary phthisis and pleurisy, and bundles up by themselves only the remaining unspecified diseases of this system. Similarly, our tables give much more information as to the prevalence and severity of wounds, accidents and injuries.

The strength of the British army was in round numbers 200,000 men, half of these men were on the home stations, and two-thirds of the other half in India. Malta and Gibraltar were the largest of what may be called the small military settlements the former with nearly 8,000 and the latter with 5,000 men. Canada had only 1,500.

The admissions on sick report of the home service troops amounted to 772.2 per thousand of strength. This seems to intimate that there was much less sickness among these men than in our army during the same period, for our admission rate was 1364.78 per thousand, but notwithstanding their relatively small number of cases our British friends had 41.66 men constantly sick while we had only 42.01. The average duration of each case was with them 19.69 days, with us 11.2 days. It is seen, therefore, that the admission rate means little. Our medical officers place men on sick report for trivial disorders that do not meet with official recognition in the British army. The non-efficient rate, based on the number constantly sick, is the proper rate for measuring the relative amount of sickness in different armies, and as these rates are 41.66 and 42.01, our disability during the year must be regarded as practically the same as theirs, notwithstanding their smaller number of cases. Their death rate was 4.94, ours 8.05, but the latter includes the men who were killed in the Sioux campaign. Their rate of discharge for disability was 14.51, ours 17.23.

When we consider that the 100,000 men who furnished these statistics were stationed on what in this country would be called fancy duty, we have reason to be gratified with the comparison, for many of our men during the year were exposed to all the discomforts and insanitary conditions incident to a state of war. When the British troops on foreign stations are brought into the calculations the general death rate of their army rises to 9.13, and the constantly non effective from sickness to 55.86. Their heaviest death rate was reported from the Mauritius, 25.87, half of which was caused by enteric fever. India gave 16.36, the main factors enteric fever and cholera, and the West Indies 13.69, in part due to yellow fever. The highest non-effective rate was given by the troops in the Straits settlements, 93.48, more than half of it the result of venereal diseases. India had 80.22 constantly sick and the West Indies 75.53.

But it is with the record of the home service troops that we are chiefly interested, as permitting us to compare the morbility among our own troops with that of men who are stationed in a healthy climate and have the best medical and sanitary care. Enteric fever caused only 1.1 admissions per thousand of strength, as compared with 3.95 in the United States, but in considering these rates it is to be remembered that a large number of other continued fevers were reported in the United Kingdom many of which would probably have been called typhoid fever in this country. As in previous years, the station at which there were most cases of enteric fever was Dublin. Influenza prevailed as much in Britain as in the United States. Although the opinion is generally entertained in this country that drainage and efficient cultivation have banished malarial fevers from the British Isles, we find that there were 1.8 admissions in Scotland, 3.0 in Ireland and 9.6 in England and Wales. The greatest prevalence in the United States was 546.05 in Oklahoma, but the average of the army was only 62.63. If the sickness from all forms of venereal disease is taken together the British admission rate amounted to 197.4, and the constant sick to 15.34. Our figures compare favorably with these, only 72.46 admissions and 5.00 non-efficient, but if all our garrisons were in the neighborhood of cities, as are most of the English stations, it is possible our rates might be as high as theirs, for their highest admission rate, 280.0, in the Channel Islands, was nearly equaled by our recruits at Columbus Barracks, Ohio, who had a rate of 266.66. It is alcoholism, however, that must be regarded as the special vice of our troops when compared with the British if any faith may be placed in the statistics. Only 2.4 admission were recorded, while the United States rate was 40.01. We know that our men go on sick report when they are suffering from the effects of dissipation, but the figures fail to give us any idea of how this may be in the English ranks. We have recognized already that their trivial cases are not taken on the sick report, and a little cerebral congestion or gastric irritability due to the conviviality of the evening before may be regarded as one of the trivial cases. The admission rate for injuries was 105.1 and the mortality .70, as compared with 248.91 and 3.02 in the United States. They had a total of 19 deaths from gunshot wounds in their 100,000 men, we had 87 among our 25,000, they had 27 deaths from drowning, we 18, they 25 suicides, we 22, all of which seems to indicate that on home service Tommy Atkins has a quieter and easier life than he would have if he emigrated and took service under the stars and stripes. Out of a total of 35,678 operations of vaccination of soldiers 68·31 per cent gave perfect results, 18.87 per cent gave modified results, 12.82 were failures.

Of 6,132 recruits inspected 37.88 per cent were rejected. We are more exacting in our requirements, for of 25,050 candidates we rejected 63.84 per cent. The average British recruit is young and undeveloped, age 19.6 years, height 65.6 inches, weight 122.3 pounds, and chest measurement 33.4 inches. On account of our short term of enlistment and the inclusion of our reenlisted soldiers in the list of accepted men, our average recruit is a much better man. Age 24.43, height 67.43 inches, weight 145.35 pounds, circumference of chest at expiration 34.16 inches, at inspiration 37.02 inches.

In the appendix to the Report Brigade, Surgeon Lieut.-Colonel J. Lane Notter reviews the progress of hygiene for the year 1892. He speaks highly of the work of the Massachusetts Board of Health, and cites from a paper by Mr. Fuller on the differentiation of the bacillus of typhoid fever in water. The method of Dr. Theobald Smith for distinguishing the typhoid bacillus is also given. Special note is made of the efforts in France to reduce the prevalence of enteric fever in the army by the substitution of pure for polluted water, or in default of this, by subjecting the impure water to a filtering process by the Chamberland filter. Wherever an epidemic broke out the water supply was found to be contaminated. In 1867 the enteric fever cases numbered 6,881, since then they have been reduced 52 per cent. The filter is composed of Chamberland bougies, system Pasteur, placed in concentric circles in the inside of a metallic reservoir capable of receiving water under a pressure of three atmospheres. For a company of infantry a filter of twelve bougies is allowed, with a reservoir having a capacity of 150 liters. The officers of the medical department are responsible for the proper working of the filters.

Epidemic of Typhoid in Allegheny, Pa.—An epidemic of typhoid fever has broken out in lower Allegheny and invaded the Western Penitentiary. Two deaths in two days occurred in the prison. Eighteen other prisoners are in the hospital suffering with the disease and some may not recover. Outside the prison there are scores of cases. The drinking water pumped from the Allegheny River is given as the cause of the epidemic.

New Hospital at Kansas City.—The University Medical College of Kansas City, have leased All Saints' Hospital, and organized a new staff. Dr. B. E. Fryer is President of the Board of Managers.

The New City Hospital at Minneapolis was opened for occupancy October 1.

Health of New York —During the month ending September 30, the lowest mortality thus far of the year 1893 was reached in the city of New York The total number of deaths reported was 678, which is 53 below the average of the corresponding weeks of the past five years, and represents an annual death rate of only 18 54 for each thousand of the estimated population Notwithstanding the generally improved condition of the health of the city, however, there was an increase of seven over the previous week in the number of deaths from smallpox, which amounted to ten On account of the increase in this disease the health department is making use of extraordinary precautions, and has just secured from the Board of Estimate and Apportionment the appropriation of $3,000 for the payment of fifteen extra physicians to serve in the free vaccinating corps Dr Nagle, registrar of records of vital statistics, reports that epidemic influenza has again made its appearance in the city, a month earlier than last year During the week two deaths were recorded as due to this cause, and they are the first reported from la grippe since the week ending July 1, when there were also two fatal cases Last year the first death from it was reported October 29, and up to the close of the year the deaths amounted to twenty From January 1 to July 1 there were 182 deaths During the week there were thirteen deaths from typhoid fever, two from scarlet fever, twenty-three from diphtheria, four from cerebro spinal meningitis and eight from measles

A Simplified Formula for a Much Litigated Article —A nostrum that has been much in the papers and much in the courts, and is nevertheless still doing a considerable business, it is said, is the subject of an exposure in the *Druggists' Circular and Chemical Gazette* The object of the article is to present a prescription which, while not coming in conflict with the patent rights of any microbe destroyer, will have all the desired or desirable potency It has been declared by Dr Eccles of Brooklyn, in the journal above named, that the Radam's Microbe Killer contains sulphuric acid for its main support in the realm of germ-slaying The prescription, simplified from the analyses of Eccles and others, reads as follows

Sulphurous acid, U S P, four ounces, sulphuric acid, commercial, four drachms, muriatic acid, two to ten drops, red wine, one ounce, water, sufficient to make one gallon

In former analyses, the muriatic acid had been found in larger proportions That was "one of the best of the ingredients," as Dr Eccles reported in 1889, whereas now it is almost eliminated and sulphurous acid has taken its place Dr Eccles states later that he is informed that the formula used by the Canadian branch excludes the red wine, one ounce to the gallon

Pigmentation Treated by Tattooing —According to Dr Paschkis, in the *Archiv für Dermatologie and Syphilis*, Heft 3, 1893, tattooing may be made use of in the relief of pigmentations of the skin The material chiefly used by him has been baryta-white, which latter may be toned to the color of the surrounding integument by a judicious admixture of browns and reds A little experience, with a good eye for color, will bring about a considerable improvement of the unsightly parts

Dr Ohmann-Dumesnil of St Louis, has shown that tattooing may be removed by tattooing His method involves a new principle, namely, the digestion of the subcutaneous pigments by papoid The tattooed parts having been well washed with soap and water, a bunch of cambric needles—six or eight—bound together with silk thread is used This medical tattooing implement is dipped in glycerol of papoid, and driven with a sharp blow into the tattooed part This is repeated over the entire stain, and must be thorough to be effective A peculiarity about this method is that it causes no inflammatory reaction observed in tattooing with Indian ink or other pigments Dr Ohmann-Dumesnil considers that the digestive principle of the papoid is disseminated about the deposit of pigment thus liberating it A portion is absorbed, in a finely divided state, by the lymphatics, another part probably finds its way into the upper layers of the epidermis and thence to the surface, and in this manner the pigment disappears

Elected Mayor of Woodward —Dr Melton of Denver, Colo, was one of the "boomers" that went to the Cherokee strip, and when the land was thrown open to settlement and the people had selected their locations and erected their tents a municipal government was organized by the election of Dr Melton of Denver, as mayor, Attorney Laune of Denver, city attorney, and a board of aldermen consisting of five members, three from Denver, and two from Texas On Sunday two services were held, and Woodward has started on its career with as good and even better prospects than any settlement in the strip Following precedent, a new medical society and medical journal will doubtless soon be added to the attractions of the infant city

The Anti-Rheumatic Ring —A writer in *Science Siftings* says that two thousand years ago the Greeks believed that there was virtue in finger rings as against rheumatism Galen, in the second century, gave heed to some of the popular fancies of that day, and recommended a ring of jasper with an intaglio of a male figure wearing about his neck a bunch of herbs Marcellus, in the time of Marcus Aurelius, prescribed a ring of pure gold, with certain Greek letters inscribed thereon, to be worn for pain in the side, the circlet was directed to be worn on the side opposite to the pain The decrease of the moon was propitious to the plan of cure "And these rings," says the writer, "had quite as much medical value as those that are now being sold for the relief of rheumatism"

Bequests to New York Hospitals —The will of the late Hon Hamilton Fish provides that St Luke's Hospital shall receive $5,000, and the Bellevue Training School for Nurses $2,000 These are gifts additional to former ones made during the lifetime of the donor

Fatality Following the Administration of Chloroform —A death after chloroform occurred at the Methodist Episcopal Hospital at Brooklyn, N Y The patient, an adult male, had been brought to the hospital for the reduction of a dislocation of the arm, due to a fall from a wagon Full anesthesia had not been induced before syncope set in, which could not be removed by the restoratives used

Examinations of Manitoba University Medical Department —The program of examinations is as follows

Wednesday, Sept 20—9-12 A M Algebra, med entrance and previous supp

2-5 P M Canadian hist and geog, med entrance and previous supp chemistry

Thursday, Sept 21—Euclid, med entrance and previous supp

2-5 P M Arithmetic, med ent and Latin, prev supp

Friday, Sept 22—9-12 A M Physics, med ent, trig, prev and pass

2-5 P M Latin, Virgil, med ent, French, previous statics, pass

Saturday, Sept 23—9-12 A M Latin, Cæsar, med ent

2-5 P M Botany, med ent

Monday, Sept 25—9-12 A M Grammar and rhetoric, 1½; composition, 1½

2-5 P M Optional subject, poetical literature

Dr J L Wilcox of Springfield, Ill, has been recently appointed Collector of Internal Revenue for the Pekin district

A Cottage Hospital is to be built at Woodstock, Ont, at a cost of $10,250

THE PUBLIC SERVICES

HEADQUARTERS OF THE ARMY, ADJUTANT GENERAL'S OFFICE
WASHINGTON, September 22, 1893

GENERAL ORDERS, No 78

By direction of the Secretary of War, upon the recommendation of the Surgeon General of the Army, the faculty of the Army Medical School, established by General Orders, No 51, June 24, 1893, from this office and regulations for the government of the school are announced as follows

FACULTY OF THE ARMY MEDICAL SCHOOL

Colonel Charles H Alden, assistant surgeon general U S Army, president of the faculty, and lecturer on the duties of medical officers

Lieutenant Colonel William H Forwood, deputy surgeon general, U S Army, professor of military surgery

Major John S Billings, surgeon, U S Army, professor of military hygiene

Major Charles Smart, surgeon, U S Army professor of military medicine and director of the chemical laboratory

Captain Walter Reed, assistant surgeon, U S Army, professor of clinical and sanitary microscopy and director of the pathological laboratory

Captain Julian M Cabell assistant surgeon U S Army, assistant to professor of military surgery and instructor in Hospital Corps drill

THE COURSE OF INSTRUCTION

“The course of instruction will be for four months, and will be given annually at the Army Medical Museum, in Wasihngton City, commencing *on the 1st day of November*” *It will include lectures on and practical instruction in*—

1 The duties of medical officers in war and peace

2 Military surgery, the care of the wounded in time of war, and hospital administration

3 Military hygiene

4 Military medicine

5 Microscopy sanitary and clinical pathological histology, bacteriology, and urinology

6 Hospital Corps drill, and first aid to wounded

By permission of the Surgeon General medical officers of the Army who desire to avail themselves of the course of instruction, and who are stationed in or near the city of Washington or who have a leave of absence which enables them to attend the course may be admitted as pupils under the same regulations as apply to recently “approved candidates for admission to the Medical Corps of the Army”

EXAMINATIONS

At the termination of the course of instruction the “approved candidates for admission to the Medical Corps of the Army” will be examined *by the several professors, and their relative proficiency in each* branch will be reported by the president of the faculty to the Secretary of War through the Surgeon General of the Army

REGULATIONS

1 The president of the faculty will be responsible for the discipline of the school

2 The junior professor will act as secretary and will be responsible for all property pertaining to the school

3 A faculty meeting will be held in the office of the secretary on the first Monday of each month from October to March, inclusive, and whenever called by the president of the faculty or the Surgeon General of the Army

4 Resolutions adopted by the faculty relating to the course of instruction the purchase of books and instruments etc, will be submitted to the Surgeon General of the Army for his approval

5 The president of the faculty will submit to the Surgeon General of the Army, on or before the 1st day of April of each year a detailed report of the condition of the Army Medical School including an account of the instruction given and the proficiency of the several pupils as shown by an examination made by each professor at the termination of his course

6 The hours of instruction will be from 9 to 12 A M and from 1 to 4 P M, daily, from November 1 to February 28 inclusive, with the exception of Saturdays, Sundays legal holidays, and the week commencing December 25

7 Pupils will be required to be present during the hours designated unless specially excused by the president of the faculty or by orders from the War Department

8 When necessarily absent on account of sickness or other emergency, pupils will as soon as practicable send a written statement to the secretary of the faculty, explaining the reason for such absence

9 The laboratories and library of the Army Medical School will be open for the use of pupils during the hours of instruction designated

10 Pupils will be held strictly accountable for all instruments and apparatus issued to them for their personal use during the course of instruction, and for any loss or injury to books or apparatus belonging to the Army Medical School, when such loss or injury is due to carelessness or neglect

11 Pupils in the Army Medical School during the hours of instruction, will wear the undress uniform of the grade to which they belong, except when engaged in laboratory work, when a black cambric laboratory gown may be worn

By command of Major General Schofield

R WILLIAMS, *Adjutant General*

Army Changes Official list of changes in the stations and duties of officers serving *in the Medical Department U S Army, from September* 23, 1893 to September 29 1893

Lieut Col FRANCIS L TOWN deputy Surgeon General U S A is granted leave of absence for four months on surgeon s certificate of disability By direction of the Secretary of War

First Lieut CHARLES F KIEFFER Asst Surgeon, is relieved from further duty at Ft Meade, S D, and from temporary duty at Ft Yellowstone, Wyo and will report to commanding officer at Ft Assiniboine, Mont for duty

First Lieut WM F LEWIS Asst Surgeon will, upon being relieved from duty at Ft Assiniboine Mont by Lieut KIEFFER, report to commanding officer, Ft Apache Ariz for duty

First Lieut BENJAMIN BROOKE Asst Surgeon will proceed at once from Ft Leavenworth Kan to Ft Brady Mich for temporary duty during the absence on leave of Asst Surgeon PAUL CLENDENIN, U S A

Capt PAUL CLENDENIN, Asst Surgeon U S A, is granted leave of absence for one month to take effect from the arrival of Asst Surgeon BENJAMIN BROOKE

Marine Hospital Changes Official list of changes of stations and duties of medical officers of the U S Marine Hospital Service, for *the six weeks ended September 16, 1893*

Surgeon R D MURRAY, to proceed to Pensacola, Fla for temporary duty, August 10 1893 To rejoin station, August 18, 1893 To proceed to Brunswick, Ga, for temporary duty, September 14 1893

Surgeon P H BAILHACHE to assume charge of inspection of immigrants, August 14, 1893 Detailed as chairman of board for physical examination of keepers of life saving stations August 18 1893 Relieved from duty as inspector of immigrants, August 22 1893 Detailed as chairman of board for physical examination of officers Revenue Marine Service, September 12, 1893

Surgeon GEORGE PURVIANCE, to report at Bureau for temporary duty August 6 and 10 1893 Detailed as chairman of board for physical examination of Surgeon JOHN VANSANT August 28 1893

Surgeon JOHN VANSANT, ordered before board for physical examination, August 31 1893

Surgeon W H H HUTTON, to report at Brunswick August 10, 1893 To proceed to Cape Charles Quarantine as inspector, August 12 1893 To proceed to Brunswick, Ga for temporary duty, August 12 1893 To rejoin station, Detroit, Mich, September 10, 1893

Surgeon JOHN B HAMILTON granted leave of absence for four days, August 16, 1893 Granted leave of absence for ten days, August 29, 1893

Surgeon H W SAWTELLE, detailed as member of board for physical examination of life saving stations, August 18, 1893 Detailed as member of board for physical examination of P A Surgeon H T GOODWIN, August 22 1893 Detailed as member of board for physical examination of officers Revenue Marine Service September 12, 1893

Surgeon H W AUSTIN detailed as recorder of board for physical examination of Surgeon JOHN VANSANT August 28, 1893 To represent the Service at meeting of Pan American Medical Congress, September 5, 1893

Surgeon J M GASSAWAY, to inspect local quarantine at Pascagoula, Miss, August 23 1893

Surgeon F W MEAD, to proceed to Chicago, Ill, for temporary duty, August 9 1893

Surgeon H R CARTER, to proceed to Fernandina Fla, to inspect quarantine, and return to Bureau August 7, 1893 To proceed to Pensacola, Fla August 10 1893 To proceed to Brunswick, Ga, for temporary duty, August 12 1893 To report at Bureau, August 21 1893 To represent the Service at Pan American Medical Congress, September 5, 1893 To proceed to Philadelphia, Pa and Reedy Island Quarantine, September 9, 1893 To proceed to Cape Charles Quarantine and assume command September 11, 1893 To report at Bureau for temporary duty September 13, 1893

Surgeon W A WHEELER detailed for duty at Camp Low, August 14, 1893 To rejoin station August 22 1893 Detailed as recorder of board for physical examination of P A Surgeon H T GOODWIN, August 22, 1893

P A Surgeon D A CARMICHAEL, granted leave of absence for thirty days, August 16, 1893

P A Surgeon C T PECKHAM, granted leave of absence for twenty days, August 10, 1893

P A Surgeon A H GLENNAN, to proceed to Reedy Island Quarantine for temporary duty, August 30 1893

P A Surgeon G M MAGRUDER, to proceed to Pensacola, Fla, as inspector August 10 1893 To proceed to Brunswick, Ga, for temporary duty August 23 1893 To proceed to Beaufort, S C, as inspector, September 9, 1893

P A Surgeon J J KINYOUN, detailed as inspector New York Quarantine August 12 1893 Detailed as member of board for physical examination of P A Surgeon H T GOODWIN August 26 1893

P A Surgeon H T GOODWIN, granted leave of absence for thirty days August 10 1893 To proceed to Louisville, Ky, for duty, August 15, 1893 Ordered to appear for examination as to physical condition, August 22, 1893

P A Surgeon G T VAUGHAN, to represent Service at meeting of Pan American Medical Congress September 5 1893

P A Surgeon H D GEDDINGS to report at Bureau for temporary duty, September 13, 1893 To proceed to Brunswick, Ga, for temporary duty as inspector September 15 1893

Asst Surgeon L E COFER, to proceed to Savannah Ga, for duty, August 25 1893

Asst Surgeon C E DECKER to proceed to San Francisco Quarantine for temporary duty September 3, 1893

Asst Surgeon J A NYDEGGER to proceed to Jersey City, N J, for temporary duty, September 2 1893 To rejoin station, September 9 1893

Asst Surgeon J H OAKLEY, to proceed to Quebec, Canada, for duty, August 26, 1893

Asst Surgeon SEATON NORMAN to proceed to New York City for temporary duty, August 18 1893 To rejoin station August 23 1893 To proceed to Jersey City for temporary duty, September 3, 1893 To rejoin station September 9 1893

Asst Surgeon E K SPRAGUE to proceed to Cairo, Ill, for temporary duty, August 26 1893

ADDRESS

INTERNATIONAL CONGRESS OF PUBLIC HEALTH

ADDRESS OF THE PRESIDENT,[1]

SAMUEL H DURGIN, M D
BOSTON MASS
PRESIDENT OF THE AMERICAN PUBLIC HEALTH ASSOCIATION

As co-workers in the field of sanitary science, and its practical application to the prevention of disease and death, we have again assembled from different parts of this and other countries to join hands, and to take counsel with each other.

We have met this time under most unusual circumstances, and with surroundings and conditions of world-wide interest

The Columbian exposition marks an era in the world's history Around us are gathered the evidences of advance in all lines of industry, of talent, and of thought There has been a peace congress, a congress of religion, a congress of charities and correction and innumerable other gatherings for the purpose of comparing notes and showing the great advance in our civilization in all lines of thought and endeavor

Among those who have died since the last meeting is Dr Edward H Janes, who for twenty-seven years occupied the position of Assistant Sanitary Superintendent of New York He was also Secretary of the American Public Health Association for two years

His contributions to the first three volumes of the Transactions, were characterized by care and painstaking, and of a decidedly practical character

He was much interested in his chosen work and was a modest, upright, conscientious man

Other workers have also passed away, and tributes to their memories will be paid by the Committee on Necrology

AMERICAN PUBLIC HEALTH ASSOCIATION

The great trust which this Association took upon itself twenty-one years ago has been worthily held, and the work to which it has addressed itself in the interest of humanity, has been diligently pursued It is fitting, perhaps, at this time, when we may be said to have attained our majority in years, to take a retrospective glance of public sanitation, and to note the possible results of its application in the relief of human distress The work of the sanitarian is manifold, and deals with the most vital of our personal and social interests It deals with the air we breathe, the food we eat, the water we drink, the soil we live upon, and with the general welfare of mankind It means the investigation of the rise, progress, and decline of epidemics, and a fostering growth of works and projects designed to prevent and remove the causes of disease

AIMS OF SANITARY SCIENCE

The sanitarian concerns himself but little with the cure of disease The problem which he seeks to solve is how disease can be averted The pathologist establishes the nature of morbid processes, and his investigations suggest to us the appropriate remedy The aim of the sanitarian is to seek out and remove the cause or causes which produced these processes It has been said that preventive medicine embraces everything which relates to the physical well being of our fellowmen, so that it has to deal with all physical evils and, incidentally, many of a moral character Its object is the health, and therefore the happiness and prosperity of man

It is sometimes objected that public hygiene can not lay claim to the possession of the qualities of an exact science, that its data are too partial, its generalizations too sweeping Unfortunately some reason for this feeling exists on account of the enthusiasm of certain writers who exaggerate what is seen, guess at what is unseen, and shape their conclusions accordingly

True sanitary science, however, is built up slowly by patient observation of facts Sanitary science is not altogether of modern growth It may be said to have experienced several revivals, but its real history is almost as ancient as history itself

HYGIENE AMONG THE ANCIENTS

The ancients fought against evil smells as vigorously as the moderns A process of disinfection was adopted by Ulysses, and described by Homer Hercules too, was a practical sanitarian, but of all the ancient sanitary reformers, Moses was the most thorough and practical He gave us the principle of the modern earth closet, although the animals of the field may be said to have anticipated him in that device During the best times of Greece and Rome, public sanitation was much studied, and the supervision of hygienic arrangements was an office of dignity among the Greeks and the Romans The cleansing and disinfection of streets and sewers were placed under a high officer of state, because as Justinian tells us "uncleansed and unrepaired sewers threaten a pestilential atmosphere, and are dangerous"

Sanitary science owes something to the fathers of medicine also Hippocrates was the first sanitarian who wrote an entire book on public health, and his discourses upon pure air, pure water and pure soil are instructive reading at the present day

It is exceedingly interesting and suggestive to find these ancient writers elucidating principles which the exact investigations of our time have demonstrated to be the true foundation of sanitary science

In Mexico it has been shown that sanitary science must have reached a high degree of perfection in its history Previous to the conquest of the country by the Spaniards, the towns were thoroughly and efficiently supplied with water by the most perfect system, but the teachings of these early times were not permanently effective The magnificent civil works were doomed to suffer ruin, and the world passed through dark ages of mental and physical barbarism

---

[1] Read October 10 1893

The devastating epidemics of the middle ages which cut off one-quarter of the population of Europe are well known Filth, instead of being abhorred, was almost sanctified The monks imitated the filthy habits of the hermits and saints of early Christian times, and the early fathers commended them Even St Jerome used to praise the filthy habits of hermits, and especially commended an Egyptian hermit who combed his hair on Easter Sunday only, and never washed his clothes at all Monks up to the time of the reformation thought, or professed to think that, by antithesis, pollution of the body indicated cleanliness of the soul Practically, indeed, it might be said to have helped to it, because the odor of sanctity which infected these monks and hermits helped them to keep apart from the temptations of the world, for the world scarcely cared to come into too close contact with these odoriferous saints

MODERN SANITATION

The science of public sanitation as practiced in our day is a growth of recent years, a reaction from the ignorance and negligence of previous generations in the matter of sanitary administration This reaction may be said to have dated from 1838, when the English Poor Law Commissioners instituted an inquiry into the health of towns with a view to remove by public authority some of the evils incident to poverty for which the poor are not responsible, and which they can not themselves remedy The active movers in this work were Dr Southard Smith, Mr Edwin Chadwick, Dr Arnott and Dr Farr, and it is to their labors and testimony that much of the present enthusiasm concerning sanitary investigation and administration is due The work begun by these pioneers has been carried on with increasing zeal from that time forward It has enlisted the active interest of a multitude of intelligent, earnest men, who have patiently and persistently devoted their energies to the investigation of the causes of disease, and a constantly increasing interest is being manifested among the people concerning all matters looking toward a more perfect conservation of the public health

Employers have found that there is a financial aspect to the sanitary questions of the day, and that more work and better work can be obtained from men in health than from men diseased

Legislation has been influenced by the researches into the causes of disease, and has followed the lead of the investigators

The schools of Europe and America have one by one added to their requirements for a degree in medicine, a knowledge of sanitary science It is becoming more and more apparent that the first and largest interest of the State lies in this great agency of human power, the health of the people

What practical results have followed from all this? What has sanitary science done for man as an individual and for mankind collectively?

In the first place, it can be shown that man to-day has a greater expectation of life than any of his progenitors He may more reasonably look forward to a long life, and to a life less exposed to devastating sickness His vitality has been expanded, his strength increased and his days on earth prolonged.

From this brief review of the general subject of sanitary science let us turn to a more specific and practical consideration of some of its principles, and I will ask your attention for a few moments to the topic of *municipal sanitation*

MUNICIPAL SANITATION

The municipal health officer on entering upon his duties finds himself confronted with innumerable questions as to the sources of danger to the public health, of which he has been selected as guardian

He first pictures to himself an ideal sanitary condition, for example a clean, dry surface, a well-drained soil, good public and private sewerage, the immediate destruction or removal of all decomposable wastes, wholesome food and water supplies with a sufficient equipment to preserve all of these favorable conditions, and then his work of construction and maintenance begins

It would be impossible within the scope reasonably given to a single address to more than touch lightly upon the large number of topics, and the variety of each which falls under the care of the municipal health officer I shall, therefore, delay you by a consideration of only a few of the more important subjects which affect the health of cities.

WATER SUPPLY AND DRAINAGE

The difficulty of finding a pure and uncontaminated water supply in sufficient quantity to meet the ever increasing requirements of modern civilized life, has confronted every large city on the globe With the increase of population it is not possible to find a watershed which is not more or less polluted by the wastes of human life Our great lakes even at certain points upon their shores have become at times sources of disease And some of the cities of the old world recognizing the difficulty of procuring waters which are not contaminated by sewage, have almost by force of necessity adopted a suspicious supply, and have trusted to methods of filtration for the removal of the disease producing elements. London and Berlin afford examples of the immunity from infectious diseases attending the use of waters so filtered A variety of opinions is held among sanitary engineers as to the best method for sewage disposal The opportunty for the ultimate disposal of sewage is not the same for all cities One city has the opportunity to discharge its sewage into deep tide water under such conditions as to give rise to no evil results, while other cities are not so favorably situated It would be a safe principle to follow, however, never to discharge sewage matter into any river, lake, or body of water which is likely to be used as a source of water supply

DRAINAGE

Although I am not prepared to say that through the scientific experimentation now going on in the filtration of sewage polluted waters, the time may not come when the waters of any river or lake may be used as a source of water supply, and the sewage resulting therefrom then be returned to the streams in a state of comparative purity which will render them available for domestic uses However much we may disagree as to the ultimate disposal of sewage, there seems to be a general consensus of opinion that the water carriage system must supersede all others in its cheapness and capacity for a apid and safe translation of our sewage from its initial starting point to a proper and safe outfall, where it may be disposed of without offense and danger to the inhabitants of the city

It is generally conceded that when this material is confined within its proper channels and constantly undergoes rapid removal it is harmless, and does not deserve the opprobrious epithet which it incurs under opposite conditions, namely, when stagnating without or even within its channels

Under these favorable conditions, the problem of the ventilation of sewers becomes extremely simple by harmless open grate covers over the manholes in the streets The public sewers thus supplied with the proper and continuous incline to secure the rapid and continuous flow, are ready to receive the private drainage from dwellings and factories and other sources

The question of private or house drainage is more complex, and should be constructed only under regulations prepared by competent sanitary engineers, by plumbers who have shown their competency for such work to a proper board of examiners, and have been licensed therefore The material for this work should be strong, tightly jointed, securely trapped and ventilated above the top of the house

With a system of sewage thus supplied, the privy vault and cesspool, which have been most serious menaces to the health of cities, should cease to exist

It is easy to see that with such suitable provisions for the complete and rapid removal of all sewage, the escape of noxious emanations from the sewers into the streets and dwellings would be impossible

The conditions under which sewer gases are generated and penetrate into houses are from the stagnation of sewage, by its putrefaction when the consequent generation of poisonous vapors are favored, and the absence of sewer ventilation, by consequence of which these vapors are confined and pent up, until they acquire a sufficient degree of tension to force the barriers by which we vainly attempt to exclude them from our homes By the rapid removal of sewage, on the other hand, its putrefaction in our midst is forestalled, the generation of noxious gases within our drains and sewers is reduced to a minimum or wholly prevented The ventilation of sewers is rendered easy and harmless, and finally such air, gases and vapors as must be contained within the sewers, being no longer confined, find an easy escape into the open air

In the city of Boston our private drainage, like that in most cities, is unsatisfactory, and the cause of an immense amount of inspection, complaint and annoyance, and undoubtedly the cause of much ill-health We have statute laws and city ordinances which specify the method, material and workmanship necessary for the construction of house drainage Plans for construction and repairs are submitted to, and the work approved by, the inspector of buildings

The board of health is called upon to find defects and to order repairs, and such repairs each year number about 4,500

For the purpose of ascertaining to what extent defective conditions of plumbing exist, and to what extent traps are supplied, and water closets substituted for privy vaults, we have taken a large number of blocks of dwellings, both new and old, each season for thirteen years, and made house-to-house inspection, with the following results

Want of traps, first five years, averaged	50%
During thirteen years	32%
During the last year	22%
Defective conditions of plumbing first five years averaged	49%
Whole thirteen years	39%
During the last year	34%
Use of privy vaults, first five years	28%
For thirteen years	14%
During the last year	3%

This means not only a very poor state of plumbing, but a want of commendable progress in the substitution of a better condition It indicates poor construction and inefficient repairs

It is my opinion that the regulations, supervision of construction and repairs of plumbing should be in charge of one department The old privy vaults and cesspools, with their accumulation of filth, which were once so common, are now rapidly disappearing from the city Nearly seven thousand of these privy vaults have been demolished in as many years, and the few remaining where a public sewer abuts the premises are under orders to go The yard cesspools, which are also common nuisances, are being changed from receptacles for sink and other house drainage to those for surface drainage only

DISPOSAL OF WASTE

The removal and disposal of refuse material has become a very serious question to the city as a corporation, and to the individual citizen There are now in vogue several different methods for the disposal of the kitchen refuse, all of which are more or less objectionable In one city it is carried away and dumped into the sea, in another it is collected and sold to the farmers to be fed to swine, and in another it is removed to a distance from the city and buried or consumed by fire

In the city of Boston, where the principal part is sold to farmers, and the remainder carried out to sea, the cost of collection and transportation has reached the annual sum of one hundred and seventy thousand dollars, or considerably more than the entire appropriation for the health department, which includes the maintenance of harbor quarantine, free public baths and urinals, hospitals for contagious diseases, disinfection, public vaccination, the care of public burial grounds, the inspection of nuisances, and other incidental expenses This large cost can not be diminished by any of the present methods in use, but must necessarily be increased by the growth of population, by hauling to a greater distance, or by the process of cremation, which is now in use in many of our cities

It must be admitted that the storing of this material in our yards, and its subsequent transportation through our streets, creates a nuisance of a most disgusting character, and it seems to me it should not be looked upon by sanitarians as harmless, or as a satisfactory method of disposal, to say nothing of the enormous cost to the city

It has for many years seemed to me, that the kitchen wastes should, by some special provision in the kitchen stove, be disposed of as soon as they are formed By this means, all subsequent nuisance and expense would be avoided

The other wastes of the city which are now dumped into the harbor, and into other bodies of water, or upon vacant lots for filling, which are largely composed of combustible material, should undergo cremation, and their ashes used for filling tem, but the teachings of these early times were not permanently effective. The magnificent civil works were doomed to suffer ruin, and the world passed through dark ages of mental and physical barbarism.

The devastating epidemics of the middle ages which cut off one-quarter of the population of Europe are well known. Filth, instead of being abhorred, was almost sanctified. The monks imitated the filthy habits of the hermits and saints of early Christian times, and the early fathers commended them. Even St. Jerome used to praise the filthy habits of hermits, and especially commended an Egyptian hermit who combed his hair on Easter Sunday only, and never washed his clothes at all. Monks up to the time of the reformation thought, or professed to think that, by antithesis, pollution of the body indicated cleanliness of the soul. Practically, indeed, it might be said to have helped to it, because the odor of sanctity which infected these monks and hermits helped them to keep apart from the temptations of the world, for the world scarcely cared to come into too close contact with these odoriferous saints.

MODERN SANITATION

The science of public sanitation as practiced in our day is a growth of recent years, a reaction from the ignorance and negligence of previous generations in the matter of sanitary administration. This reaction may be said to have dated from 1838, when the English Poor Law Commissioners instituted an inquiry into the health of towns with a view to remove by public authority some of the evils incident to poverty for which the poor are not responsible, and which they can not themselves remedy. The active movers in this work were Dr. Southard Smith, Mr. Edwin Chadwick, Dr. Arnott and Dr. Farr, and it is to their labors and testimony that much of the present enthusiasm concerning sanitary investigation and administration is due. The work begun by these pioneers has been carried on with increasing zeal from that time forward. It has enlisted the active interest of a multitude of intelligent, earnest men, who have patiently and persistently devoted their energies to the investigation of the causes of disease, and a constantly increasing interest is being manifested among the people concerning all matters looking toward a more perfect conservation of the public health.

Employers have found that there is a financial aspect to the sanitary questions of the day, and that more work and better work can be obtained from men in health than from men diseased.

Legislation has been influenced by the researches into the causes of disease, and has followed the lead of the investigators.

The schools of Europe and America have one by one added to their requirements for a degree in medicine, a knowledge of sanitary science. It is becoming more and more apparent that the first and largest interest of the State lies in this great agency of human power, the health of the people.

What practical results have followed from all this? What has sanitary science done for man as an individual and for mankind collectively?

In the first place, it can be shown that man to day has a greater expectation of life than any of his progenitors. He may more reasonably look forward to a long life, and to a life less exposed to devastating sickness. His vitality has been expanded, his strength increased and his days on earth prolonged.

From this brief review of the general subject of sanitary science let us turn to a more specific and practical consideration of some of its principles, and I will ask your attention for a few moments to the topic of *municipal sanitation*.

MUNICIPAL SANITATION

The municipal health officer on entering upon his duties finds himself confronted with innumerable questions as to the sources of danger to the public health, of which he has been selected as guardian.

He first pictures to himself an ideal sanitary condition, for example: a clean, dry surface, a well-drained soil, good public and private sewerage, the immediate destruction or removal of all decomposable wastes, wholesome food and water supplies with a sufficient equipment to preserve all of these favorable conditions, and then his work of construction and maintenance begins.

It would be impossible within the scope reasonably given to a single address to more than touch lightly upon the large number of topics, and the variety of each which falls under the care of the municipal health officer. I shall, therefore, delay you by a consideration of only a few of the more important subjects which affect the health of cities.

WATER SUPPLY AND DRAINAGE

The difficulty of finding a pure and uncontaminated water supply in sufficient quantity to meet the ever increasing requirements of modern civilized life, has confronted every large city on the globe. With the increase of population it is not possible to find a watershed which is not more or less polluted by the wastes of human life. Our great lakes even at certain points upon their shores have become at times sources of disease. And some of the cities of the old world recognizing the difficulty of procuring waters which are not contaminated by sewage, have almost by force of necessity adopted a suspicious supply, and have trusted to methods of filtration for the removal of the disease producing elements. London and Berlin afford examples of the immunity from infectious diseases attending the use of waters so filtered. A variety of opinions is held among sanitary engineers as to the best method for sewage disposal. The opportunty for the ultimate disposal of sewage is not the same for all cities. One city has the opportunity to discharge its sewage into deep tide water under such conditions as to give rise to no evil results, while other cities are not so favorably situated. It would be a safe principle to follow, however, never to discharge sewage matter into any river, lake, or body of water which is likely to be used as a source of water supply.

DRAINAGE

Although I am not prepared to say that through the scientific experimentation now going on in the filtration of sewage-polluted waters, the time may not come when the waters of any river or lake may be used as a source of water supply, and the sewage resulting therefrom then be returned to the streams in a state of comparative purity which will render them available for domestic uses. However much we may disagree as to the ultimate disposal of sewage, there seems to be a general consensus of opinion that the water carriage system must supersede all others in its cheapness and capacity for a rapid and safe translation of our sewage from its initial starting point to a proper and safe outfall, where it may be disposed of without offense and danger to the inhabitants of the city

It is generally conceded that when this material is confined within its proper channels and constantly undergoes rapid removal it is harmless, and does not deserve the opprobrious epithet which it incurs under opposite conditions, namely, when stagnating without or even within its channels

Under these favorable conditions, the problem of the ventilation of sewers becomes extremely simple by harmless open grate covers over the manholes in the streets The public sewers thus supplied with the proper and continuous incline to secure the rapid and continuous flow, are ready to receive the private drainage from dwellings and factories and other sources

The question of private or house drainage is more complex, and should be constructed only under regulations prepared by competent sanitary engineers, by plumbers who have shown their competency for such work to a proper board of examiners, and have been licensed therefore The material for this work should be strong, tightly jointed, securely trapped and ventilated above the top of the house

With a system of sewage thus supplied, the privy vault and cesspool, which have been most serious menaces to the health of cities, should cease to exist

It is easy to see that with such suitable provisions for the complete and rapid removal of all sewage, the escape of noxious emanations from the sewers into the streets and dwellings would be impossible

The conditions under which sewer gases are generated and penetrate into houses are from the stagnation of sewage, by its putrefaction when the consequent generation of poisonous vapors are favored and the absence of sewer ventilation, by consequence of which these vapors are confined and pent up, until they acquire a sufficient degree of tension to force the barriers by which we vainly attempt to exclude them from our homes By the rapid removal of sewage, on the other hand, its putrefaction in our midst is forestalled, the generation of noxious gases within our drains and sewers is reduced to a minimum or wholly prevented The ventilation of sewers is rendered easy and harmless, and finally such air, gases and vapors as must be contained within the sewers, being no longer confined, find an easy escape into the open air

In the city of Boston our private drainage, like that in most cities, is unsatisfactory, and the cause of an immense amount of inspection, complaint and annoyance, and undoubtedly the cause of much ill-health We have statute laws and city ordinances which specify the method, material and workmanship necessary for the construction of house drainage Plans for construction and repairs are submitted to, and the work approved by, the inspector of buildings

The board of health is called upon to find defects and to order repairs, and such repairs each year number about 4,500

For the purpose of ascertaining to what extent defective conditions of plumbing exist, and to what extent traps are supplied, and water closets substituted for privy vaults, we have taken a large number of blocks of dwellings, both new and old, each season for thirteen years, and made house-to-house inspection, with the following results

Want of traps, first five years, averaged	50%

DISPOSAL OF WASTE

The removal and disposal of refuse material has become a very serious question to the city as a corporation, and to the individual citizen There are now in vogue several different methods for the disposal of the kitchen refuse, all of which are more or less objectionable In one city it is carried away and dumped into the sea, in another it is collected and sold to the farmers to be fed to swine, and in another it is removed to a distance from the city and buried or consumed by fire

In the city of Boston, where the principal part is sold to farmers, and the remainder carried out to sea, the cost of collection and transportation has reached the annual sum of one hundred and seventy thousand dollars, or considerably more than the entire appropriation for the health department, which includes the maintenance of harbor quarantine, free public baths and urinals, hospitals for contagious diseases, disinfection, public vaccination, the care of public burial grounds, the inspection of nuisances, and other incidental expenses This large cost can not be diminished by any of the present methods in use, but must necessarily be increased by the growth of population, by hauling to a greater distance, or by the process of cremation, which is now in use in many of our cities

It must be admitted that the storing of this material in our yards, and its subsequent transportation through our streets, creates a nuisance of a most disgusting character, and it seems to me it should not be looked upon by sanitarians as harmless, or as a satisfactory method of disposal, to say nothing of the enormous cost to the city

It has for many years seemed to me, that the kitchen wastes should, by some special provision in the kitchen stove, be disposed of as soon as they are formed By this means, all subsequent nuisance and expense would be avoided

The other wastes of the city which are now dumped into the harbor, and into other bodies of water, or upon vacant lots for filling, which are largely composed of combustible material, should undergo cremation, and their ashes used for filling

STREET ENGINEERING

The construction and care of our public and private streets have a sanitary side to be considered, especially when we remember the considerable proportion of the area of our cities which they occupy, and the frequent unsanitary condition in which we find them While the construction of streets is almost purely a matter for the engineer, the health officer has frequent cause to complain of their filthy condition Most streets in all cities present a more or less unclean and offensive surface This condition may be due to a faulty pavement, want of pavement, or a lack of care, which is supported by a popular notion that an unclean and muddy condition of the streets has no appreciable effect upon the public health Macadamized streets where much used, are unclean and offensive most of the time

It would be in the interest of the public health, a cleaner atmosphere, greater public convenience and economy, if all of the much used streets of our cities were paved with material which would present an even, durable and non-absorbent surface

The private alleyways are not only disowned, but generally uncared for by the city For the most part they are found to be unpaved, uncleaned, and a source of much complaint Any attempt on the part of the health officer to cause these places to be cleansed by the abuttors is attended with great difficulty, delay and frequent disappointment It would be far better to place these private ways in charge of the city, and tax the people for properly paving and keeping them clean

MORTALITY STATISTICS

Under the head of *mortality statistics*, the health officer finds a valuable guide to important sanitary work, although it is to be regretted that much of the data found under this head is untrustworthy These mortality tables, properly prepared will show the extent of mortality, and to what extent it is excessive in any portion of the community, and its relationship to age and nationality They will also show us the nature and causes of the diseases which occasion the excess of deaths and to what extent, and by what means, these diseases are preventable

This work begins with the physician, and ends with the registrar of vital statistics Many physicians perform the duty of certifying the cause of death with great care and exactness while others perform the same service with very little knowledge of the disease of which the person died, and with corresponding ignorance of the use and value of correct mortality statistics

Unfortunately in many States there is no legal discrimination between the duties and privileges of the educated and the totally ignorant practitioner of medicine The registrar who receives these certificates should be a well educated physician, with considerable experience so as to be able to reject fraudulent and worthless certificates Every one who has had experience in the registration of mortality reports, understands how difficult it is to secure correct data from irresponsible persons The cause of these shortcomings is partly insufficiency of diagnosis, due either to the difficulties inherent in obscure cases, or to imperfect medical training, and partly to a lack of conscientiousness in the performance of registration whose objects and importance are not appreciated

Obscure cases will occur in the practice of every physician, and due allowance must be made, and yet after reasonable allowances have been made, there still remains a degree of carelessness for which there is no excuse

It is a common thing to find on death certificates instead of the morbid process which caused death, such indefinite information as "disease of bowels," "disease of brain," 'disease of skin," "stomach disease," "ascites," "convulsions," "dropsy," "fever," "debility," "teething," "inflammation," "infantile," "heart failure," and other unlikely causes too numerous to mention, and which ought never to be used upon the records as causes of death

In my own city, such certificates are rejected, and a competent physician sent to view the remains, and consult the family or friends of the deceased for information, with which to make a proper certificate

It is to be noted, however, that information gathered in this way can not be regarded as wholly trustworthy, and often results in the statement of "*unknown cause of death* "

It would be in the interest of correct mortality statistics if the registrar could be authorized, in case of insufficient information, to cause such postmortem examination by a competent physician as will enable him to record the true cause of death

An examination of the mortality statistics will also betray the fact that we have an excess of deaths from contagious diseases and from diarrheal diseases among children, and while these facts open up a wide field of labor for the municipal sanitary officer, we shall have time to mention but a few of the most troublesome of these diseases

INFECTIOUS DISEASES

Smallpox, through the great discovery of Jenner, the ease of making an early diagnosis and its perfect and easy control by isolation and disinfection, is now one of the easiest and rarest comparatively of the contagious diseases with which we may deal

Now and then our legislatures are obliged to listen to the petitions of a few anti-vaccinationists for the repeal of compulsory vaccination laws I have too much faith, however, in the intelligence and sound judgment of our people to believe that these wholesome and necessary provisions will ever be effaced from our statute books

We should not, however, in the absence of smallpox in our country, allow ourselves to grow indifferent to the necessity of keeping the susceptibility of our people to smallpox exhausted by means of early and successful vaccination of infants, and the subsequent and most important revaccination of adults

The mention of cholera, like that of smallpox, strikes terror to the people of this country, and while the deaths from these diseases are infinitely small, the fear of them has served the municipal health officer in securing almost unlimited facilities for their prevention and control, which means may be largely converted to the care of other more common and destructive contagious diseases

We have in diphtheria and scarlet fever, diseases which are not only endemic in most of our cities and large towns, and of most difficult control, but diseases for which there is as yet no known prophylactic It is easy to say, and it is equally true, that perfect isolation and disinfection in all cases would soon annihilate the two diseases, but here is where the great difficulty begins We do not know where the infection is, in a very large percentage of cases, and therefore can not make anything like a complete application of our disinfecting agents

The diagnosis of diphtheria and of scarlet fever is not always possible in their early but contagious conditions, even by our best physicians, but with the multitude of ignorant and indifferent so called practitioners of medicine, who are called to attend such cases, and the many instances of mild attacks which do not attract attention, to say nothing of the semi-popular prejudice against the hospitals, we have the causes of the lack of information to the sanitary officer, the possession of which might lead to the control of the diseases

These diseases are spread largely by children while in the early stages of the illness, or having mild and unsuspected attacks, and by those who are prematurely released from isolation through ignorance and fraud, and allowed in the streets and in our schools

It would be out of place, as well as presumptuous on my part, to delay you at this time with the details of necessary public interference which would secure a mitigation of the prevalence of these two diseases I will say, however, that I believe in early and continued hospital isolation and that all cases should be supervised, and released from isolation only by medical officers appointed upon merit by the health authorities, the same medical officers to be inspectors of schools, in which there is much valuable work to be done in detecting the early symptoms of contagious diseases, pointing out the many unobserved and growing defects in development and disabled senses of the children, reporting to the board of health the overcrowded and unsanitary condition of the school room, inspiring an interest and pride on the part of all teachers to develop an aptitude in detecting early symptoms of disease, defective senses and deformities in children, and in developing a more popular interest in the needed reforms in school hygiene

At a very small cost, we might bring to bear the powerful influence and unoccupied energies of a large corps of talented young physicians, aided by over thirty-five thousand teachers, for the public and individual welfare of nearly thirteen million children in the public schools of the United States

Consumption, the most destructive malady to the human race in our country, has received the necessary attention of the bacteriologist He has demonstrated to us satisfactorily, the cause of the disease, the methods of its transmission, and the means for its prevention

I am sorry to say that as practical workers in public sanitation, we have sadly neglected to apply the means which we believe would prove effectual in largely abating the prevalence of tuberculosis

The isolation of all persons suffering from consumption, would be impracticable and perhaps unnecessary, but the use of small sputa cups containing a disinfectant, at home, and bits of absorbent napkin used and securely concealed in traveling, to be burned or otherwise disinfected on returning, should at least be urged by public health officers, and popularized as much as possble

In this way we should try to counteract the indiscriminate and disgusting habit of careless spitting in all public and private places, where the sputa are soon dried, and in the form of dust, start on the mission of deadly infection

It is interesting in this connection, to note the fact that from experiments conducted with the tubercle bacilli, the sputa from consumptive patients have been found to retain their infective power for several years, also the fact that at a recent international congress on tuberculosis, one of the questions discussed was the necessity of obligatory cremation of the remains of consumptives

Earth worms, it was urged, bring to the surface bacilli which infest the dead body, and in dry weather they may be inhaled in the form of dust. This, it is suggested, is the reason why the health resorts of the south of Europe are centers of tubercular contagion

Drs Lortet and Depugnes of Lyons, related cases of such infection, and described experiments which they made which led them to demand obligatory cremation They mixed the sputa of consumptives in earth which they placed in pots A month later the earth worms in them were tubercular, and the earth they passed through communicated the disease to animals

Other experiments were made by placing earth worms on the graves of those who had died of consumption, and it is said the results were confirmatory of the possibility of contagion being conveyed in this manner

CREMATION

It should not be necessary to urge the sanitary claims of cremation for dead bodies before an assemblage of intelligent sanitarians There are in this country already thirty-two cremation societies, fifteen crematories, and in the last five years there have been over two thousand incinerations

Typhoid fever, like cholera, has been studied most persistently and profitably in connection with our water and food supplies, and we shall have the pleasure of listening to a discussion of the causation of typhoid by infected milk at this congress

HABITATIONS FOR THE POOR

Tenement and lodging houses are subjects for the constant watchfulness of the health officer, and they are too frequently found in an overcrowded and filthy condition They are principally occupied by the poorest classes of people, including the newly arrived emigrant, whose habits of cleanliness are of the lowest order

It becomes necessary to limit the number of occupants in such buildings on a rule of a prescribed number of cubic feet of space to each individual, by placards posted in each room, compelling frequent scrubbing and disinfection of floors and walls, burning much of the old bedding, frequently disinfecting the remainder by steam, watching them by night and prosecuting every violation of your prescribed rules

CONCLUSION

Turning in conclusion from the more onerous everyday duties of the municipal health officer to topics of greater popular interest, we find an increasing growth of public sentiment in all parts of the country favoring the municipal provision of large public parks, free public baths, small open spaces and open air gymnasiums for the enjoyment and sanitary welfare of the masses of people whose whole time is spent in the toil of our large towns and cities Much of interest and encouragement might be said as to the immense patronage and benefit of these magnificent privileges if time would allow, but

I pass over these and other important topics which, I doubt not, will receive that careful attention and discussion their importance demands during the congress which is now open

ORIGINAL ARTICLES

THE TREATMENT OF GRANULAR LIDS

Read before the Section on Ophthalmology, at the Forty fourth Annual Meeting of the American Medical Association

BY C B BLUBAUGH, M D
PARKERSBURG, W VA

Gentlemen —As an introduction to my article, the treatment of granular lids, I will say that I live in a portion of the Ohio valley where the soil is very sandy for miles from the river on both the West Virginia and Ohio sides To this fact I attribute, to some extent, the unusual prevalence of the disease in that locality During the past two years I have been so unfortunate as to have had 205 cases of more or less severity to treat Of this number 125 were treated with good results by the method I give you to-day, and the rest by all the usual plans of treatment recommended without, in some cases, the success I had hoped for I find that Druitt, in 1848, suggested scarifying the granulations, then, after a few days, he used lunar caustic on the granulations and applied citrin ointment to the palpebral edges In 1836, Mackintosh applied blisters behind the ears and dropped wine of opium in the eyes Gross used Goulard's extract for awhile, but soon quit it, as he found that it encrusted the cornea and produced mechanical obstruction, he then advised shaving off the granulations and applied sulphate of copper or a solution of nitrate of silver, twenty to sixty grains to the ounce of water Fenner used a strong decoction of phytolacca and considered the treatment especially good where there was a rheumatic diathesis or severe pain around the eye Dixon dusted the enlarged and inflamed follicles and papillæ with sugar of lead, but relies chiefly on hygiene and tonics to improve the general health, he says of all local treatment, the application of the undiluted liquor potassæ to the palpebral granulations, as suggested by Dr Bader, has been most successful It seems to act by saponifying and dissolving away the hypertrophied tissue Carter uses the *lapis divinus* daily or on alternate days according to the severity, and alternating occasionally with tannin or acetate of lead For isolated extreme hypertrophy the actual cautery has been used with success

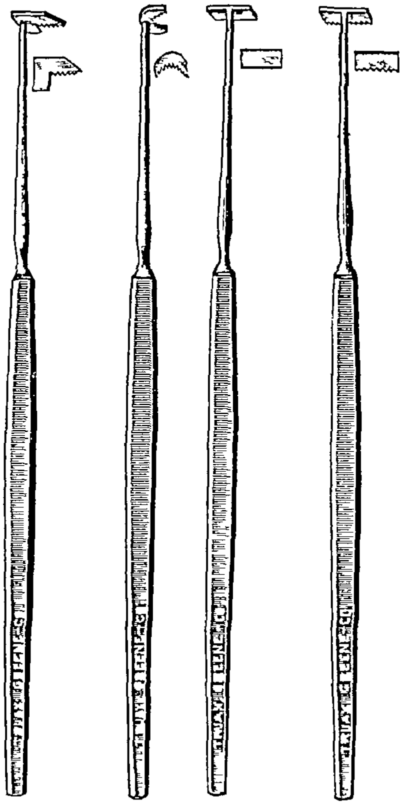
The ordinary,general treatment of the disease is nitrate of silver and sulphate of copper Arlt and Stromeyer called attention especially to the fact that these remedies were not intended to chemically destroy the granulations, but were to be used to maintain a certain degree of hyperemia in order to cause their absorption I think this important fact has, to a certain extent, been lost sight of, and they have been used to chemically destroy the hypertrophied papillæ I have seen so many ugly thick lids, with the whole mucous surface a cicatrix, presenting the condition known as xerophthalmia, and certainly due in a number of cases to the use of these drugs, that I have laid them aside entirely

In my own treatment the four little instruments I have here, play an important part, as with them the chronic granulations are removed

No 1 has a smooth edge and is used to scrape off slight granulations where there is no general hypertrophy

No 2 is the same general shape but has a file-like edge and is used in more severe cases

In everting the lids we frequently find the granulations thickest and hardest to remove just where the lid curves at the edge of the cartilage, here I use the curved instrument No 3



Above this, still, and near the retrotarsal fold, granulations are frequently found which neither of the instruments mentioned will reach, for these I use No 4, which has a long rake set at right angles to a shorter one, and will reach the high granulations without trouble, while the long rake is removing the upper granulations the shorter one will remove those situated on the curve Where the whole surface of the lid is hypertrophied presenting a gelatinous, granular mass, I have had, occasionally, to use the scissors After removing the granulations as thoroughly as possible, I give my patient a simple astringent wash, regulating its strength by the severity of the case, a lump of alum which I direct to be rubbed on the everted lid as the case may demand and let him go home In some very kind cases I have had to see the patient but once, in a number of them two to eight visits have been necessary In all my cases I look to the general health of the patient and, unless some special diathesis is present, I have found the best tonic to be a mixture of phytolacca and rumex crispis, especially where the cornea is involved In the majority of trachoma cases, pannus is present to a greater or less extent For such a condition where the cornea persists in remaining opaque, inoculation with pus from an active case of ophthalmia has been tried and with some success, as has also the jequirity bean; *abrus precatorius*, a Brazilian plant Gruening scrapes the cornea with a small knife, removing the opacity Where these all fail the cornea remaining opaque and vascular, peritomy or syndectomy has been done by a number of operators In my own practice I have used jequirity bean twice, in one case the result was all that could be desired In the other I had to work so hard to save the eye that I have not since entertained a kindly feeling for our Brazilian acquaintance In my other cases of pannus, from slight to total, I have had my patient spray the eye with a solution of tannin and boracic acid in glycerin and camphor water daily, and in addition wash the eye twice daily with a bichlorid solution A large number of cases of pannus vasculosa disappear when the granulations are removed without any special treatment The results have been peculiarly satisfactory in all the cases and the point I wish to make, in closing, is the fact that I have used neither nitrate of silver nor sulphate of copper in any case Of course I scrape off the granulations only in chronic trachomatous cases

407½ Market Street

Dr J L Thompson—I would like to know if when a case comes to us in the first stages we should commence hoeing and scraping at once? In other words, should it be done in the acute stage of the disease, or only after it has become chronic?

Dr Scott—I can see no advantage in this treatment over that of expression It is simply carrying out the same thing, and I am sorry to say that this plan of treatment has not been satisfactory with me I have used it fully a dozen times, but with very little satisfaction, and in each case had to resort to the jequirity to obtain the desired result

Dr LeMond—I think I have treated within the last year near one hundred cases of chronic granular conjunctivitis, a number of which have been treated with Noyes' method of operating I press the follicles, squeezing the morbid contents of the parts, doing it gently but firmly I always avoid, as near as possible, not to tear or lacerate the conjunctiva The sooner you get rid of the spurious material the better it will be for your patient I usually follow this operation with a mild solution of bichlorid of mercury, using it as a bath for the eye about every three hours I also direct my patient to use hot water, as hot as can be borne, from nine to ten times a day five minutes at a time, I find it very much better than cold water in these cases Where I have not followed with the bichlorid treatment I prescribe a saturated solution of boric acid which I think also acts nicely Among these cases I have had the very best results from this course of treatment I think in all cases that have assumed a frog pawn condition we should have no hesitancy in resorting to Prof Noyes' compression, in fact, I think it is the rational thing to do I am aware that some oppose this method of treatment, but so far as I have found, among those who oppose it are men who have done the operation possibly once and in some instances not a single time

Dr Murrell—In my practice I have had many cases of granular lids I think we have more cases of this trouble and in a worse form in the South and West than in the East The oculists being few and hard to reach they go on without treatment until the disease gets in its worst form They come to us with lids shortened and suffering with blepharospasm and we find it necessary to relieve the pressure by performing a canthotomy, I have never performed it on any case where I have regretted it and have had as many as two hundred cases of granular lids myself during the year The treatment used is such as is suited to the particular case In suitable cases I use Knapp's expression forceps principally, sometimes Noyes', but the grattage I do not like Not every case is suited to the forceps treatment I have cured many cases by one single treatment with the forceps, followed by the use of the boracic acid solution four times daily I then direct the patient to use hot water as hot as can be borne three times a day letting it remain for half an hour at a time There are various other remedies we resort to but to be successful with any of them we have to first relieve the pressure on the eyeball by performing a canthotomy

Dr Dunlavy—It is my misfortune to meet a great number of granular lids It appears to me that there can be no law laid down as to how to treat a considerable number of them There is a certain class that can be treated successfully by the conservative method, while there is another class in which nothing short of surgical interference will be of any effect I use Knapp's forceps, Noyes' forceps or any forceps that I have in my case, my thumb nail or any other means by which I can destroy the granular tissue I am not one of the number who believe the subsequent reaction is beneficial, but we can not expect to do any surgical work without this reaction The method of surgical interference, that of making a canthotomy, as referred to by Dr Murrell is often one of the best steps where there is pressure from the lid, and we can not do it any too early If the granulations are at all chronic we might begin with our surgical means at once A class of cases kept well under antiseptic treatment will give very little trouble With regard to patients getting well with one application we have all seen them get well with scarcely any treatment at all

Dr Prince—We all have our views as to the surgical treatment, but if a case comes to us and we have it in the acute stage it seems we ought to do something for it before it finally gets to the chronic stage About two years ago my attention was called to a paper published in the *Ophthalmic Record* by Dr Hodges in which he recommended the following remedy for granulated lids There are two solutions used, nitrate of silver 1 dram, water 1 dram and glycerin 2 drams, marked No 1 Iodid of potash 1 dram, water 1 dram and glycerin 2 drams, marked No 2 Take 3 drops of No 1 and 6 drops of No 2, mix well and apply to the everted lid I am not sure whether there is anything in the iodid of silver or not, but I am sure from two years experience that in acute trachoma by the use of this remedy twice a day a cure is effected in a considerable portion of the cases within six weeks

Dr Savage—I will say that the Hodges' mixture has been a wonderfully good treatment in my hands I hardly know how I could have gotten on without it We not only have the iodid of silver and the iodid of potassium in the solution, but we have a third ingredient, the nitrate of potassium, as a result of the reaction Thinking that the virtue of the mixture might be due to the germicidal effect of the nitrate of potassium, for three months I have been prescribing this alone with a view of deciding this point My experience in the use of the nitrate of potassium alone for this period of time strengthens my belief that Hodges' mixture has for its effective ingredient the nitrate of potassium I use it in the strength of grs xx to xxx to distilled water 1 ounce

Dr Muncaster—I have seen a number of cases treated with expression and the conclusion I have come to is that Knapp's roller forceps have been better than anything I have ever seen After the operation I give the patient a solution of boracic acid and direct that it be used every few hours during the day, and also direct him to use hot applications several times daily, and have usually gotten good results

Dr Dudley S Reynolds—I fear the gentlemen have confounded widely different conditions, and have entirely overlooked the question of the stage of advancement at which the treatment begins I use no scarification, no scraping and no cauterizations In the trachomatous and lymphoid forms, expression by Knapp's forceps undoubtedly proves successful in many cases The hypertrophoid papillæ of the lining of the lid and retrotarsal folds are not to be treated this way without great aggravation of the disease In the first stages of papillary blepharitis I prefer the solution of bichlorid of mercury and chlorid of ammonium, suggested by McKenzie as a cleansing wash in purulent conjunctivitis As the purulent conjunctivitis always precedes hypertrophy this may be recognized as an entirely rational plan of treatment, varying the proportions of the bichlorid and ammonium chlorid I often apply the crystal of muriate of ammonium directly to the everted lid, pressing it gently but firmly for a few seconds at a time This may be done without pain by a previous application of a solution of cocain In some chronic cases an ointment of the yellow oxid of mercury acts well I know of no uniformly successful plan I, nearly always, as Dr Murrell has suggested, practice some modification of canthotomy in the very bad cases whether acute or chronic

Dr Blubaugh—I think I have been a little misunderstood in regard to the use of these instruments I do not use them in every case of granular lids, but I have not used nitrate of silver or sulphate of copper in any case In answer to Dr Thompson I will say that I do not do the hoeing and scraping in recent cases I have in a number of cases used some mild astringent wash and if these granules remain I rub the lid with a lump of alum There are a number of cases in which this is successful, but in other cases where the granulations remain I pick up my little hoe and go at it Dr Baker said the cases were a little more numerous in our part of the country than in Cleveland We have in our country that light, sandy soil and I think that starts cases which develop later on into granular lids or trachoma from lack of any treatment or attention A large number of these cases were from a portion of the State far from a railroad and where physicians were not numerous Quite a number had been affected for years and had had absolutely no treatment I would like to ask Dr LeMond and also Dr Reynolds if they have any cicatricial tissue after pressing out the granules with Knapp's forceps?

PHLYCTENULAR OPHTHALMIA

Read in the Section on Ophthalmology at the Forty Fourth Annual Meeting of the American Medical Association

BY DUDLEY S REYNOLDS, A M, M D
PROFESSOR OF OPHTHALMOLOGY, OTOLOGY AND MEDICAL JURISPRUDENCE IN THE HOSPITAL COLLEGE OF MEDICINE MEDICAL DEPARTMENT OF THE CENTRAL UNIVERSITY OF KENTUCKY

Phlyctenular ophthalmia has been so variously described by writers and teachers it would seem but fair to assume that each may have been faithful in describing that form most frequently observed in his practice Believing no form of phlyctenular ophthalmia should be regarded as a merely local form of disease, calling for local treatment alone, I am led to introduce the subject in its clinical aspects It is certain the herpetic disease described by Stellwag is just as much a local manifestation of constitutional dyscrasia as are the serpiginous ulcers, or the more common conoidal masses of lymphoid cells described by the old writers as scrofulous and syphilitic ophthalmia It is very important to distinguish between the phlyctenular diseases of miasmatic and malarious localities, and those observed in strumous, rachitic and syphilitic subjects According to some writers it would be difficult to determine the syphilitic from the non-syphilitic cases, but syphilitic keratitis rarely ulcerates, yet it is nearly always attended by photophobia, by anemia and other manifestations of disturbed nutrition In all forms of circumscribed inflammation it may be fairly assumed the processes of zymosis are going on, fermentation being, in fact, an essential feature of all localized inflammations

Change of residence, change of diet, in fact, any change in the modes of living result sometimes beneficially Phlyctenular disease of the cornea, like that of the limbus conjunctivalis, fluctuates according to the state of the patient's general health and nutrition, consequently a great deal has been claimed for local treatment in such cases In some circumscribed abrasions of the corneal epithelium a small gray speck is seen, called phlyctenular keratitis, often cured by a single drop of atropin solution, just as it would have been by a drop of boric acid solution or anything which would tend to diminish the morbid sensibility in the abraded spot. The more common types of this disease are observed in the early stages as conoidal elevations, surrounded by dilated blood vessels The oldest cells in the cone break down first, leaving a vesicular appearance at the apex of the cone, presently the walls of the vesicle rupture and the ulcerated stage is present, meantime the eye is morbidly sensitive to light and the patient, if the disease be in the cornea, is harassed with pain and disturbances of the digestive organs with more or less loss of appetite An aperient containing calomel followed by quinin often cures the patient in three or four days' time I have frequently observed this course in cases which had been subjected for weeks to local treatment of calomel, mydriatics, myotics and ointment of yellow oxid of mercury, so much in vogue with some of our brother specialists

Foreign bodies in the cornea often drop out and are washed away with the tears, leaving an epithelial abrasion which in persons of previous good health will disappear without treatment If infection of this wound should occur the indications of this state are so marked as to mislead no ordinarily careful clinical observer The treatment in such cases should, of course, be local and at the same time vigorous If, however, this is observed in children with fever, or even in an adult, constitutional disturbances call for constitutional treatment independently of the disease in the eye

It is not always easy to discover the cause of phlyctenular ophthalmia, just as it is often difficult to determine the syphilitic from the non syphilitic subjects among the poorly nourished children which are observed at the public clinics everywhere It is never safe to rely upon what is known as the history of the case as related by the family, and if I were not addressing myself to a body of gentlemen many of whom have at times engaged in the general practice of medicine, I should say the statements of the family physician are just as misleading and unreliable

If your patient is the subject of inherited syphilis and has phlyctenular ophthalmia you should not be able to discover the fact by the condition of the eye alone I have often observed phlyctenular keratitis as a complication of preexisting interstitial keratitis.

Thus the conditions stated in the description of inherited syphilis in Mr Hutchinson's famous prize essay, can not apply to a very large number of cases, and especially in children whose permanent incisor teeth have not yet appeared

That state of overloaded lymph channels, with enlarged lymphatic glands, at one time supposed to be indicative of tuberculosis or inherited syphilis, and for a long time denominated scrofulosis, is now known to be brought on by excessive indulgence in the glucose types of food, even starvation itself is attended by an abnormal increase in the lymph stream, and enlarged lymphatic glands

The late Dr Henry F Formad, of the University of Pennsylvania, demonstrated certain structural peculiarities in the lymphatic system of subjects of inherited syphilis, the children of tuberculous parents, and in those with acquired struma His researches show conclusively that some of the forms of mal-nutrition in infants result from faulty development in fetal life

Inherited syphilis, localized zymosis, mechanical obstructions in the capillary lymph tubes of the conjunctiva may each set up local changes which pass through all the varying stages of cell proliferation, disintegration, ulceration, and partake of those characters called phlyctenular disease, because of their circumscribed nature

Dr J L Thompson, of Indianapolis—The causes and conditions which bring about phlyctenular inflammations vary very much I meet with it far more frequently during the hot summer months than in the winter Living in an inland city where we have many sultry days and sleepless nights, cases of phlyctenular ophthalmia are the bane of childhood, especially where the strumous diathesis prevails I place no reliance in any one remedy unless it be change of climate When my patients have the means to do so, I urge upon them a change to the lakes, the mountains or to the coast No sooner is this change made than improvement takes place Where my patients are poor I urge upon them to keep as cool as possible, cleanliness, avoiding indigestible food, candies and all such trash Yellow oxid of mercury ointment in cases where the cornea is not ulcerated, and treatment to the alimentary canal when indicated Very often does this diseased condition hang on with one relapse after another until autumn weather sets in, nor does it stop here but repeats itself the following summer

Dr F C Hotz—I do not agree with Dr Reynolds that phlyctenular ophthalmia is of syphilitic origin in the sense in which we regard interstitial keratitis as a local manifestation of inherited syphilis Phlyctenular ophthalmia is undoubtedly influenced by any kind of malnutrition, and the treatment of these patients is unquestionably assisted by correcting any disorder of the digestive organs or any other condition which may affect the nutrition But local treatment is by far the most essential measure for subduing the present inflammation

Dr Connor—The best treatment of many cases of phlyctenular disease of the conjunctiva or cornea is a residence in a well conducted children's hospital Results are here obtained in a few days that require weeks or months of very many of these cases Proper food, sleep, pure air and regularity in treatment are very real factors in these results Of course, local and general medication are helpful, but the most efficient remedy is a dose of a good children's hospital I have found this same remedial agent a most satisfactory element in the management of many of the allied affections of the eye in children

Dr Zeigler—My experience coincides with that of Dr de Schweinitz The immediate origin of phlyctenular attacks is almost always nasal, and not constitutional, as stated by most authors Examination usually reveals associated lesions of the nostril and eye of the same side If you treat the nose the eye will frequently recover without treatment A simple treatment is by the nasal spray, and intranasal applications of tr benzoin comp two or three times a week, (applied with cotton on a wire applicator) You may use a simple wash for the eye An ointment of hydrarg ox flav may prove useful

Gastro-intestinal disturbances may originate or exaggerate the attack, by causing reflex irritation of the nose

I agree with Dr Thompson when he recommends regularity of diet, and especially in children who are continually eating cakes and candies which perhaps do more harm than any other variety of food But a worse error in diet is the coffee and tea furnished by parents to their children, which soon saps their vitality The worst examples of this unhygienic regimen are seen in hospital practice, and my formula has invariably been "no tea, no coffee, no cakes and no candy" These alone may bring recovery Of course the bowels should be kept regular Salt water baths are excellent for toning up the relaxed surface of the body

Dr LeMond—It seems very singular indeed that a body of men, banded together in the same work and being composed of the very best men in different parts of the country, would have such a variety of views concerning the same subject And yet it is true

I believe in trying to build up the general health in this phlyctenular trouble and the child, I tell the mother, should be bathed and rubbed down thoroughly twice a week, until a good healthy action is brought about by the skin, to give it good substantial diet, light supper but lots of good sweet milk In regard to local treatment I use usually, the yellow oxid of mercury ointment I apply this from three to six times a week, owing altogether to the severity of the case and if there is much photophobia and inflammatory action I prescribe also atropin, instilled into the eye, three or four times a day so as to guard against any ciliary complications

I protect the eye with dark glasses or by keeping the child in doors during the day and have it take its exercise in the twilight of the evening If this does not arrest the ulcer in a few days I apply directly to the ulcer, once a day a solution of argentum nitras, neutralizing the amount that might reach the healthy tissue with a solution of chlorid of sodium

Under this course of treatment, from one to three weeks, my patient usually gets well I have, in a few instances, applied the galvano cautery and have got very good results from that treatment However, in the majority of cases I think this latter treatment a little too heroic

In applying the yellow oxid of mercury if you will mix a drop or two of water with the same amount of mercury it gives us a perfectly smooth solution, which it is impossible to obtain by simply mixing with the vaselin

Dr Murrell—I use the yellow oxid locally and have frequently had complaint from its use In reference to the method of preparing the yellow oxid I think I can suggest something better than mixing the powder first with water and then with vaselin My druggist for a long time used this method but at my suggestion substituted olive oil instead, which readily blends with the fatty excipient and gives a uniform ointment

In concluding the discussion Dr Dudley S Reynolds said

Mr President, I am quite surprised that Dr de Schweinitz should have misunderstood my remarks in reference to syphilis I am sure no one would make a diagnosis of syphilis from any peculiar appearance presented in any form of phlyctenular ophthalmia by reference to the eye alone

I have seen cases which I felt sure were due to syphilis, but other manifestations of syphilis, so distinctly characteristic as to leave no room for doubt were present, without reference to the disease of the eye

I quite agree with Dr Gradle that nasal diseases are frequent complications, upon the relief of which, the successful treatment of the eye depends

My neighbor, Dr Thompson, points out the value of climatic changes He frequently observes a large number of these cases in the early summer, and if he is able to induce the parents to take the child away from the city, and remain until fall, he frequently finds no other treatment necessary I feel impressed these cases fall into the hands of general practitioners, and get quinin, iron, the iodids, baths, outdoor exercise, and the mineral waters, which, with change of diet bring on such improved states of nutrition as to completely remove the constitutional dyscrasia, upon which the local disease in the eye depends

Dr Connor of Detroit, expresses an important truth in his statement that hospital cases frequently relapse on returning home, and speedily recover when subjected to the hygiene and improved diet of the hospital

Eczematous eruptions of the face, and especially about the eyelids, should be treated as complications merely, and not as causes of phlyctenular disease, the yellow oxide of mercury ointment is no doubt valuable, in fact I am sure it is in eczematous complications, and in some chronic ulcerated forms of keratitis, but those are not to be counted as ordinary types of phlyctenular disease

The point I tried to make plain in my paper is, that all local diseases known as phlyctenular ophthalmia, not clearly due to traumatic causes, should be regarded as local manifestations of a constitutional dyscrasia, that constitutional treatment is always demanded, and local treatment if applied at all, should be mild and soothing, and never stimulating or irritating in character

Syphilitic cases are to be known by other manifestations independently of the disease in the eye, and call for certain modifications in the constitutional treatment only

Dr Gradle—A number of cases of phlyctenular ophthalmia will get well as quickly whether treatment be applied or not In other cases local applications change the course of the disease in such a decisive manner for the better, that no doubt can occur as to their efficacy In many of these cases where we can get a definite history we will find that the phlyctenular keratitis is preceded by a purulent rhinitis, and by proper attention to the nose the patient will often recover more promptly than if the nasal trouble is ignored Others are caused by adenoid growths in the pharynx and the removal of same very decidedly affects the case

While admitting the great importance of proper hygiene, rational diet, fresh air and baths in the prevention of relapses I can not say that any personal observation of mine or statements by others have ever seemed to me conclusive as to any influence of so-called constitutional treatment in the course of the attack

Dr de Schweinitz—If I correctly understood Dr Reynolds that inherited syphilis was one of the causes of phlyctenular ophthalmia I doubt if evidence to prove this assertion can be produced In so far as the treatment of phlyctenular ophthalmia is concerned, which I prefer to denominate phlyctenular kerato conjunctivitis, while agreeing with all that Dr Reynolds has said concerning the advisability of good food hygiene and proper diet, I believe local measures are of the utmost importance I am particularly impressed with the necessity of treating the naso pharynx in cases of phlyctenular ophthalmia of relapsing character, not alone because of the almost constant association of catarrhal rhinitis, tumefied turbinals, or adenoid vegetation, which of themselves are probably causative factors, but because their removal often suffices to remove the disease, to prevent a relapse and directly to improve the whole physical constitution of the patient The disorders of dentition bear some relationship to phlyctenular keratitis Borrowing an expression from Harrison Allen, I would advocate the exploration of the entire "cephalic mucous membrane" whenever this disease is manifest, and the correction of any anomalies which may be discovered

In closing, I would refer to the relation of astigmatism to this disease as taught by Martin of Bordeaux, who has pointed out that phlyctenular kerato conjunctivitis is common at that age of life when the habits of the child become such that the effects of accommodative strain, the result of an astigmatic cornea, are likely to become apparent

Dr Baker—This is an important subject to the practical ophthalmologist and is one on which I should like to see more stress laid as to the general treatment The main thing in the treatment of phlyctenular ophthalmia is the improved general health of the child and it is not from any direct interference with the eye I think the best thing that can be done is to take these children away from their families and put somewhere where they can be treated and dieted just as you would have them I believe that one of the best remedies is arsenic in small doses, one drop three times a day of Fowler's solution

Dr Gibson—I wish to say only a word on this line, in regard to the diet of children I think this a very important point, at least it has been in my experience We should study the diet of the children, then we know how to get at the treatment If we take away from a child what it likes it is not going to do well We may give maltin or extract of malt to aid in the digestion of starches Let them have their bread and potatoes Cod liver oil will supply the food in the line of meats You can get most children to use cod liver oil without trouble

---

PURULENT OPHTHALMIA FROM THE STANDPOINT OF ITS SPECIFIC MICROBIC CAUSE,

WITH A PLEA FOR A MORE ENERGETIC, RATIONAL, ABORTIVE TREATMENT WHERE POSSIBLE

Read before the Section on Ophthalmology, at the Forty fourth Annual Meeting of the American Medical Association at Milwaukee

BY ALFRED HINDE, M D

SENIOR SURGEON EYE AND EAR DEPARTMENT, CENTRAL FREE DISPENSARY OPHTHALMOLOGIST TO THE NEUROLOGICAL CLINIC AND ASSISTANT TO THE CHAIR OF OPHTHALMOLOGY IN RUSH MEDICAL COLLEGE, CHICAGO, ILL

Progress is the watchword of ophthalmology, and we all wish to avail ourselves of the garnered harvest of the bacteriologist, and apply his well ascertained facts to the orbital corner in which we are specially interested So much ink has been used, so many brains employed for so many years on this threadbare subject of purulent conjunctivitis that it would seem to be an act of supererogation to again ask attention to it Yet when we consider its vast importance as a frequent cause of blindness, another modest effort to simplify the apparently different conclusions of equally authoritative observers is excusable

Further than a bare hint that the gonococcus occasionally resides in the discharges of an efflorescent purulent ophthalmia, little is *usually* mentioned of this specific microbic cause in the great mass of contemporaneous literature It would seem that since Neisser[1] of Breslau, in 1879 discovered this diplococcus, the peculiarities of its existence, growth, action and habitat have not been as *universally* considered by our clan as the importance of the subject demands, and to this fact is mainly answerable the diverse methods of treatment of the results of this potent microorganism It is, therefore, in the literature of the genito-urinary tract that we find our richest rewards of observation, and in the subsequent lines the statements made are largely drawn therefrom

As special students we must extend our observation to all the data of the microbe under consideration, for it is now scarcely contestable that the majority, if not all, the cases of purulent conjunctivitis are produced by this coccus,—as proven by careful microscopical research, and through cultivation or implantation experiments by competent bacteriologists

This bacterium is variously described as spheroidal,[3] ovoidal, hemispherical[4] or biscuit-shaped with one surface flattened It appears in pairs, or multiples, with the flattened surfaces toward each other, hence a diplococcus It multiplies by elongation and division, and a single germ gives rise to a colony In size it varies with age but its usual dimensions are about 1 6 micro-millimeters from[6] pole to pole, and in width about 0 8 to 0 6 *micro-millimeters* It thrives on mucous surfaces, and best on those covered with a cylindrical or a modified cylindrical epithelium It stains readily with the basic anilin dyes Pus spread out in a thin layer on a cover glass, dried naturally, passed rapidly and momentarily through a spirit flame to coagulate the albumen, immersed for one minute in a solution of[7] 1 part methyl-blue, 33 parts alcohol and 66 parts water, then well washed in water, dried carefully, and *mounted* in (turpentine) balsam or glycerin, and examined with a magnifying power of 450 or more diameters will demonstrate the blue-stained microbe, if present Steinschneider,[8] however, regards Gram's[10] method of staining microorganisms as necessary to the satisfactory study of the gonococcus, as a positive characteristic of it is that by this plan it is not stained, "while nearly all other diplococci found in the urethra are colored thereby " Roux[9] also agrees with this conclusion after a study of eighty-six gonorrheal patients, and Senn adds "The entire certainty of this test is rendered absolute by the observation of the further characteristic of the gonococci, namely, *that they are found within* the pus corpuscles."

Dr J Schutz[11] of Frankfort, advocates a method of staining that depends on the known resistance of the gonococcus to acetic acid after being colored with methyl-blue Preparing the cover glass in the usual way it is allowed to remain for five to ten minutes in a cold, filtered saturated solution of methyl-blue in 5 per cent carbolic water It is then water washed and dipped for one moment, or until one, two, three, can be counted, in acetic acid water (acid acet dil mv aq 20 cc) and immediately washed in pure water The acetic acid decolorizes all other organisms except the gonococcus which remains distinctly blue "Double staining with safranin can now be done when *the gonococci* and epithelial cells show a blue color, while the pus cells and their nuclei are found salmon colored "

Experimental cultivation of the gonococcus is difficult save in the serum of human blood, or less well in animal serum, either solidified by sterilized gelose (M Hueppe[12]) Inoculation with pure cultures[13] invariably produces gonorrhea in man In drying *the microbe loses its virulency*, and pus containing it after dessication, fails to produce the specific[14] inflammation either when applied dry or when moistened with water Again, the microbe does not long retain its virulency when kept moist, yet removed from its chosen soil, for Welander in four implantation experiments made three with pus from one to several days old and in these the results were negative In the fourth the pus was removed only three hours before and kept at body temperature, and on the third day after implantation smarting was complained of, and two days later a typical gonorrhea developed Two experiments in which the pus was exposed to a temperature near freezing resulted negatively Wertheim, however, claims that their virulency is not lost rapidly in artificial culture media, for he found a four weeks' culture in human blood, still very virulent He says the microbes must be protected against dessication and that they develop better when protected from oxygen[15] The artificial cultures grow only at body temperature and the colonies *readily die off* Subcutaneous injection of gonorrheal pus in animals produced no reaction[16] and in twenty-four hours afterwards the cells remained unchanged but the gonococci had disappeared Wertheim[17] claims that it can produce peritonitis in some animals and he found the microbe in the walls of the abdomen, in the epithelium and connective tissue, and that it travels like other pyogenous germs by way of the lymphatics

During research the gonococcus has been found in the urethra, bladder, kidney, perimetric abscesses following gonorrhea, in the purulent contents of joints in gonorrheal synovitis, in the conjunctiva, rectum, uterus, cervix, vagina, vulva and in Bartholin's glands Its principal habitat in the pus corpuscle is more important than its diplococcus form When implanted on the mucous membrane of the urethra or on the conjunctiva, its first growth takes place upon the epithelial layer and the deeper parts are not invaded until, by inflammatory or chemotactic changes, the intercellular cementum has been dissolved, thus loosening up the epithelia and opening up *inter* and *sub* epithelial passages Without these changes deep or sub-epithelial infection can not occur, and Bumm[18] claims that on account of the dense, compact epithelial layer of the adult vagina that a true gonorrhea of this tract is impossible, while it may occur in children He further states that ' The stratified epithelium of the bladder is impenetrable to the gonococcus " In the incipient stage of infection the secretion is merely an exaggerated physiological one of thin mucous fluid somewhat serum-like in appearance, and containing mainly exfoliated epithelia and a few pus cells with the diplococci present on the surface of the epithelia and a few are found within the pus cells Soon the microbe penetrates the sub epithelial lymph spaces and the inflammation extends more deeply and after the second or third day the secretion becomes profuse and contains fewer epithelia with pus cells greatly in excess, and from 2 to 3 per cent of the latter contain gonococci and usually two or more in a corpuscle From now on the pus cells increase relatively in number to the epithelia, and more of them contain the microbe until 20 per cent. possess them. When the subacute stage is reached the epithelia increase in number and the pus cells become fewer yet a greater proportion of the latter contain the gonococci, and more numerously. In the fourth week the epithelia are most numerous and possess the microbes while the pus cells are few. It is claimed that the cell nucleus can be invaded, and that the cell may also become distended and ruptured by the number of the contained cocci. Extra-cellular gonococci are also plentiful. Human serum we have noted as the choicest medium for their growth, hence the virulency of this infection in purulent conjunctivitis.

This bacterium produces suppuration only on continuous mucous surfaces, and it results from the irritative effect on the tissues of the absorption of the chemical substances produced by them, because pus cells emigrate to the surface before the microbes have reached the vascular layer. These same pus cells are but dead embryonal cells, or leucocytes, attracted by phagycytosic action to the infected focus in order to prevent the ingress of the cocci, or to destroy them, and by embodying them within their own walls they become ptomaine poisoned themselves and destroyed. The inflammatory exudation of cells, fibrin, and serum tends to loosen up the epithelia and aids their exfoliation. Cessation of suppuration is not synonymous with stoppage of infection for increased irritation may again arouse the chronic inflammatory process still present.

The gonorrheal micrococcus and that of purulent ophthalmia are now almost universally conceded to be identical. Prof. Haab[19] of Zurich, claimed: "That the gonococcus is always present in the secretions of purulent ophthalmia and that it is never present in the simple inflammatory, or catarrhal form." Widmark[20] examined the secretion in twenty-four cases of purulent ophthalmia and found the cocci in most of them, free in the secretions, in the pus and the epithelial cells. He believes that during the incubative stage the microbes are only attached to the epithelial cells. This latter observation is in line with that of other examiners and most forcibly suggests an early, rational and effective treatment while the specific microbic cause is encompassable and before its ptomaine poisoning of the tissues has resulted in serious complications—due to impairment of their normal physiological resistance. Before exudative and immediate pressure have resulted in cellular necrosis and molecular death of the ocular tissues, thus producing an *infection atrium* for the entrance of the ordinary pyogenic microbes. Here the omnipresent streptococcus, and may be the staphylococcus, often take up the work of ocular destruction after the gonococcus indirectly has opened the doorway of tissue infection and reduced the resistance of the remaining cornea, and alas! they too often never end until the visual organ is utterly destroyed. That the gonococcus is a pus microbe in the usual sense is still debatable ground, yet cases have been recorded where this microbe has entered the circulation and produced metastatic abscesses after mural implantation in parts distant from the original focus. In these now numerously recorded cases of systemic infection, with septico-pyemic symptoms and occasionally fatal results we have most often only the fever and the *locus minoris resistentiæ* produced by the absorption of the toxins of the gonococcus, followed by the localization of the floating pus microbes in the affected tissues of various regions of the body. In short, a secondary infection. The gonococci have, however, been demonstrated in the contents of such abscesses, and are also found in the effusions into the joints of gonorrheal rheumatics, and in the blood of such patients.

This condition of secondary infection suggests the query of the harmonious co-existence of the pyogenous microbes and gonococci on the same site. Here there appears to be apparently contradictory statements.

That secondary infection can occur was first positively proven by Breiger[21] and Ehrlich in 1882, where the pathological product of one infection aids in the localization of another kind of pathogenic germs,—one microbe preparing the soil for the growth of the other. The gonococcus it is claimed,[22] can so change the resistance of the tissues of the genito-urinary tract, of women especially, so that an easy invasion of pathogenic microbes occurs. As an example is given by Bumm a pure gonorrhea of the vulvo-vaginal glands which after the suppurative stage remains chronically inflamed for months and is followed by sclerosis and atrophy of the glands. But if a purulent infection is added the gland enlarges and suppurates but the contents of the abscess possess no gonococci. "The pus only contains the pyogenic staphylococcus, which has exterminated the gonococcus." Bumm also claims that a cystitis following a gonorrhea, that a suppurative parametritis after gonorrhea is analogous to a gonorrheal bubo, and all are examples of mixed infection, with pus microbes, because: "The gonococcus expends its action in the superficial layers of the mucous membrane exclusively." Delafield and[23] Prudden, however, after describing the location of the gonococcus and its subsequent inflammations write: "Under these complicating conditions the gonococcus may occur alone, or in association with the pyogenic cocci."

Prof. Haab[24] in Zurich, often met with cases of iritis, irido-cyclitis and conjunctivitis in gonorrheal patients, "without any direct transmission of the urethral discharge" and in such no gonococci were found in the conjunctival secretion and the attacks were mild and readily overcome. These cases were examples of rheumatic and not microbic inflammations. He reports one case of mixed infection with metastatic joint abscesses, etc., with loss of one eye and great impairment of the other, together with persistent fever of many weeks' duration, and threatened death.

Dr. Bedford Brown[25] of Alexandria, Va., records a case of gonorrhea followed in three weeks by gonorrheal synovitis of both ankles and knees, with violent inguinal lymphadenitis of both sides, septic endocarditis, and "deep seated pain in the eye without conjunctivitis." The final result on the vision of the affected eye is not stated, and this is unfortunate because it may have been a metastatic suppurative choroiditis followed by phthisis bulbi,—a not very uncommon affection of the eye in cases of septico-pyemia arising from systemic infection with pus microbes.

A personal observation of such result may be given in the following case.

A child twenty-seven months old was taken sick with scarlet fever of mild character. Two days after the onset of the attack the left knee joint became inflamed and the left eyeball was slightly reddened, and the submental lymph glands enlarged. The knee joint suppurated and was opened two weeks later and its purulent contents removed and finger-sized drains left *in situ* and treatment continued in the usual way. The irregular fever which varied from 99 degrees to 105 degrees F. still continued and septic pneumonia, or other focus, was suspected as the cause of its persistence, but nothing positive could be made out. At the end of six weeks from the onset of the sickness, and after the institution of marked marasmus, the left eyelids swelled up and the eyeball became red and chemotic, and supposedly painful. The appearance was that of a mild suppurative choroiditis and as the inflammation disappeared, the eyeball softened and began to shrink and nine weeks later this eye was sightless, half-sized and boggy. The neck glands did not suppurate and the septic fever gradually subsided and uninterrupted recovery occurred.

Innumerable cases of secondary infection after gonorrhea have been recorded and, amongst others of less severity, one occurred in my own practice in which, after an imperfectly cured gonorrhea, a prolonged cystitis with general septic infection followed, associated with an irremovable and intermitting fever, and exhaustion almost fatal. Recovery set in slowly on improvement of the urethral and bladder condition, the systemic microbes most probably being thrown out through the kidneys, as at no time could any local suppurative focus be outlined in any organ. One year later, after a new exposure and infection with the gonococcus, the cystitis recurred followed by septic infection and a left pneumonia of small area at first, and of insidious onset, and multiple subcutaneous abscesses, together with a profuse suppurative otitis media of the right ear. No crisis occurred but the lung inflammation continued to spread until fever and heart exhaustion, practically unaffected by all treatment, resulted in a fatal issue. In this case the gonococcus twice prepared the soil for the successful implantation *in loco* of the commoner streptococcus pyogenes—as this is the microbe, that is almost solely and invariably found in these cases.

The gonorrheal microbe, however, can not always be blamed for the production of the *locus minoris resistentiæ* within the ocular tissues. It is well known that floating pus microbes are present in the blood current of many marasmic patients. All that is necessary for the localization of these cocci in the ocular tissues is a reduction of the normal physiological resistance of some portion of the eyeball. In these non-resistant cases this can be brought about readily by inflammatory changes and operative procedures."[26]

Here we have an explanation of those eyes lost in a suppurative process after perfect healing of the corneal wound, subsequently to a smooth cataract extraction. We must invigorate such patients and remove these bacteria, before we add operative insult to their tissues. Again, it is well known that pus microbes can long remain quiescent in old osteomyelitic foci and years later become virulent when suitable conditions of tissue injury arise for their multiplication. Have we not a parallel to these surgical cases in those old sympathetically and otherwise inflamed eyes that flare up into acute inflammation as soon as we attempt to remove the old exudate, or perform an iridectomy? The imprisoned microbes are set free by our manipulations and are again surrounded by a suitable environment for activity and reproduction. For diagnostic purposes the presence of the gonococcus within the pus corpuscle implies a gonorrheal origin of the eye affection, and yet by so many, and devious paths it reaches the conjunctiva that in some cases its source is past finding out, and we may, unfortunately, be led to question the specific character of the conjunctivitis, unless we look for and find the microorganism. For a moment we may consider the immediate and remote sources of infection. The essential element is carried to the conjunctiva usually on fingers, linen, or sponges, may be from unclean wash basin or other object in auto or other cases, accidentally or intentionally. Dr. Symes,[27] in the meeting of the New York Academy of Medicine, Nov. 10, 1890, called attention to the supposition of the ignorant gonorrhea sufferers who, in some instances believe that they can get rid of the disease themselves by giving it to somebody else, and at the same meeting Dr. Robert Abbe[28] said that Dr. Willard Parker had given expression to a similar observation. Twice patients of my own have asked me if this unclean intent was not a fact.

Age does not limit the possibilities of an infective source, for catarrhal inflammation, usually of gonorrheal origin, of the vaginal mucous membrane is not infrequent[29] in the newborn, and the infant and youthful vulvo-vagina often equals the adult tract as a prolific focus of infection—the parents, or adults, being the initial source of all such cases. Moreover, the normal puerperal vaginal secretions will not[30] produce a specific catarrhal inflammation of either the vulvo-vagina or the conjunctiva. Potts[31] examined ninety six cases of purulent vulvovaginitis in children, a majority of whom were under five years of age, and he believed that they were all of some specific infection, and examination of the discharge usually revealed the gonorrheal microbe, and only three cases were due to direct gonorrheal infection. Prochownick[32] found the cocci in seventeen out of twenty-one similar cases, and in these urethritis was a prominent symptom. Sanger[33] thinks that pyosalpinx and pelveo-peritonitis of young virgins is possibly due "To a gonorrhea contracted in childhood through indirect infection." Spaeth[34] in twenty-one cases of vulvo-vaginitis in girls from three to eleven years old found gonococci in the pus of fourteen, and the urethra escaped in the non specific cases. On investigating the source he found that the mother had gonorrhea in eleven, the father in two, and violation had occurred in three of the children. Gonococci are most numerous, he says, in the urethral discharge of adult females with gonorrhea.

Dr. Van Arsdale,[35] at the New York Academy meeting already referred to spoke of three cases in young female children, the youngest being only ten months old, and said that he saw about ten such cases yearly and attributed the infection to sleeping with parents. Dr. R. Abbe reported a gonorrhea in a boy three and one half years old, contracted from a nurse, and gonococci were found. Dr. Hugo Feleki of Buda-Pesth, before the twenty-fourth meeting of the Hungarian physicians and scientists at Kronstadt, recently held that blennorrhea is much more common in women than is generally supposed, and its consequences more far reaching than would appear The women are infected in the first days of matrimony by husbands supposed to be but not actually cured of a chronic gonorrhea He claims that the urethral inflammation may exist for some years without secretion showing, and yet will provoke in women a typical gonorrhea

From the foregoing, the genitalia of the female would appear to be the most fruitful source of infection, and mothers and nurses the most probable starting point On this account conjunctival inflammations in females should always be regarded with greater suspicion than in males, and I have very frequently remarked the onset of a purulent conjunctivitis in adult females commencing soon after the initiation of the regular menstrual flow—the auto infection being most probably due to unclean fingers in infected subjects For obvious reasons in both sexes a commencing right eye inflammation alone is more liable to be specific than simple From such frequent possible sources of infection as we have here shown, together with the great frequency of the presence of the gonococcus in the purulent discharge from the genital canal, it would seem to be injudicious in practice to doubt the gonorrheal origin of all our cases of purulent conjunctivis Better for our patient's safety if we immediately consider the graver diagnosis and institute correspondingly effective measures of relief

We have fixed the cause of the disease and located its exact position in the epithelial layers of the mucous membrane, and in those portions of the conjunctival sac covered with a cylindrical or a modified cylindrical epithelium, viz, the palpebral portions and that of the fornices, the very parts that give evidence of the greatest inflammatory reaction Whereas the ocular or scleral conjunctiva and the surface of the cornea remain practically unaffected, because of their compact, stratified, epithelial layer, until pressure necrosis results in ulceration and secondary infection

A good prognosis depends upon adequate treatment in the early periods of the disease, and before ocular complications occur

Prophylaxis is advocated and abortive treatment resorted to in purulent ophthalmia of the newborn eye Why is it not equally advisable in all eyes so affected irrespective of age? Logic and sound judgment point undeniably in such direction In all these purulent cases there is a period of apparently simple catarrhal inflammation associated with a lachrymal-mucous secretion A time during which the microbes are only on the surface of the epithelial cells and before the ptomaine poisoning of the tissues has resulted in attracting the emigrating leucocytes from the capillaries to the surface of the mucous membrane

The general practitioner is the most favored in seeing these cases in this stage and, unfortunately, he fails too often to recognize its import, and either neglects treatment or prescribes the usual zinc solution, and the case is too often not referred to the specialist until complications have arisen and fear possesses the medical mind *Without microscopic diagnosis no one can foretell the limits of a conjunctival inflammation when seen in the earliest stage! Any case may become purulent after sufficient time has elapsed, if the necessary microbe has been implanted!* Careful inquiry during the incubative period of these cases often gives positive evidence of a proximate gonorrheal focus, in men especially Whereas, in women, beyond eliciting the information of the omnipresent vaginal discharge, an inquiry is usually negative In busy practice we can not easily stop to stain and examine with microscope the discharge in every case of conjunctivis *Can we resort then to any therapeutical procedure in all such cases that will prove adequate in the purulent and at the same time harmless in the simple inflammations? We can most assuredly* The genito-urinary surgeon has authoritatively advocated the abortive treatment of a gonorrheal inflammation in his own domain, and briefly we will refer to his conclusions At a late meeting of the International Dermatological Congress Prof Neisser[36] still maintains the etiological importance of the gonococcus That microscopic discovery of the microbe in the secretions of gonorrhea is essential to a correct diagnosis That it is only in the first stages that the virus is accessible in the superficial layers of the epithelium and is then easy to treat His aim is to prevent an acute changing into a chronic urethritis, and referring to treatment states "It should therefore be commenced as early as possible after infection "

(*To be continued*)

Duels Better Fought in the Early Morning—The *St Louis Globe-Democrat* is our authority for saying that the best time for going into battle is just before breakfast That paper gives us the following item

"Dr Bernays greatly interested Surgeon General Sternberg by a proposition he laid down that when a man is shot in the abdomen shortly after eating a hearty meal the danger is much greater "A case of that kind should be operated upon in every instance," said Dr Bernays "If the bowels are empty, or nearly so, the same wound may be treated without operation "

"Applying that theory to soldiers?" remarked the Surgeon General tentatively

"I would say they ought to do their fighting before breakfast," put in the specialist

From time immemorial, the early morning hour has been the chosen time for the duello, for the "settlement" of private quarrels It is a logical arrangement, and moreover the appetite for breakfast is not sharp until after the quarrel has been appeased

METHYL-VIOLET—ITS PLACE IN THE AFFECTIONS OF THE EYE

Read before the Section on Ophthalmology, at the Forty fourth Annual Meeting of the American Medical Association

BY FLAVEL B TIFFANY

KANSAS CITY, MO

Since the day I first read and translated Prof J Stilling's articles on the subject of methyl-violet as they appeared in the *Revue General d'Ophthalmologie* in the year 1890, I have almost daily resorted to the drug as one of the remedies in the treatment of the various affections of the eye For perhaps a year or more from the time this drug, as a therapeutical agent, was introduced by Prof Stilling (as is the case with most other new remedies indorsed by authority), it was extensively discussed in all medical literature throughout the land Many if not all ophthalmologists tried it in one form or another in one disease or another, and some were pleased with it while others were disappointed Some were satisfied of positive results and added it to their list as a good and reliable remedy Others were disappointed, getting as they believed no good effect so discarded, denouncing it as without merit

When my attention was first called to the therapeutic properties of this agent, it happened that I had several patients on hand suffering from serious diseases of the eye, such as suppurative inflammation of the uveal tract, which had resisted all known treatment ordinarily used, and were marching on to the destruction of the eye In these cases the methyl-violet certainly checked the disease and in some of the cases I believe it saved the eyes In my enthusiasm and from Stilling's glowing account of its positive antiseptic qualities as an indemnity against all pyogenic influences, taking but the slightest attenuation to prevent all decomposition and putrefaction in any and all conditions, I employed it in nearly every affected eye that came to my public clinic as well as that of my private practice.

I tried it in all forms of conjunctivitis, in simple catarrhal ophthalmia, phlyctenular, granular and purulent ophthalmia, and in the different forms of iritis, dacrycystitis, hyalitis, disease of the cornea as the different forms of keratitis, ulceration of the cornea, in diseases of the choroid, in fact, there is scarcely a disease or affection of the eye in which I did not use methyl-violet Not, perhaps, from my credulity or great faith in its panasite properties, and yet if it was the non-irritant and searching antiseptic that was claimed for it, taking for its predilection the germ of all activity, paralyzing and destroying all pyogenic bacteria and believing as we do that the etiology of disease is of some form of microbe, it would not be wondered at that in my eagerness I should give it a thorough trial which I did In many diseases I have found it most efficient, while in others non-efficient, being as it were perfectly nil In some I have found it positively harmful, acting as a decided irritant In some cases where it has been long continued I found that it produced pain and soreness of the globe and in some instances I believe atrophy has followed in consequence of its continued use

In most forms of conjunctivitis it is non-reliable In purulent ophthalmia, as of the newborn or gonorrheal, its action is so uncertain as to make it unreliable, in some instances it has worked like a charm, acting as an antiseptic and dispelling purulency like magic, in others it seems to have no effect, or if any that of an irritant In one case of ophthalmia neonatorum where the baby's eyes were doing fairly well, but not being quite satisfied I resorted to the use of methyl violet, suddenly the eyes grew worse and they went from bad to worse and in spite of all I could do the cornea sloughed and both eyes were lost

I have been disappointed in its efficacy in trachoma In this disease it is entirely nil, or has been in my hands, with very few exceptions I recall, however, one or two cases where in trachoma with blennorrhea of a chronic persistency, resisting all ordinary treatment, as of the trachoma forceps, brushed with the toothbrush, etc, by the use of methyl-violet a speedy cure was brought about

There is one form of conjunctivitis and that one too that is most obstinate, frequently resisting for many months all treatment, where the methyl-violet has in my hands and with the proper systemic treatment worked speedy cures This is phlyctenular conjunctivitis In nearly all forms of keratitis that frequently extend over a period of ten to eighteen months before a cure can be brought about, and then at the best, conicity of the cornea with myopia, I have with methyl-violet cut short the disease where the cornea was so densely opaque as not to admit of any perception of the iris or pupil In absolute blindness due to dense opacities of the cornea, I have succeeded in clearing the cornea in as many days as ordinarily requires months with the old treatment

In ulceration of the cornea it is a most valuable remedy, next in efficacy to the thermo-cautery In suppurative iritis from its penetrability, non-irritant and antiseptic properties, as well as of a mydriatic it is of great value In hypopyon it acts like a charm cutting short the suppuration Soon after it is dropped upon the cornea you will see the pus in the anterior chamber taking on the violet stain, and in a few hours the pus begins to diminish in quantity and frequently have I cleared the chamber of quantities of pus in a few days, where panophthalmitis was imminent In hyalitis and all affections of the uveal tract it is efficient, and in one case that I had diagnosticated as melano-sarcoma of the choroid, the tumor by the use of methyl-violet was held in abeyance, and in one case of glioma of the retina the methyl-violet arrested the growth and as long as the child was under observation, (for several months), the tumor gradually diminished

To sum up, the affections of the eye in which methyl-violet seems most efficient and reliable are the following phlyctenular conjunctivitis phlyctenular keratitis, interstitial keratitis, ulceration of the cornea, abscess of the cornea, hypopyon, all forms of iritis (especially if combined with atropia) in diseases of the choroid, as choroiditis and hyalitis, tumors of the choroid and tumors of the retina and in chronic leucoma

Among those affections in which it seems to be non-reliable or contra indicated, are most forms of conjunctivitis, trachoma, marginal blepharitis, purulent ophthalmia and pannus

The form of the drug that I employ is the solution 1-2000 to 1-1000 in strength, occasionally I have employed as strong a solution as 1-500 The pomade has not been at all satisfactory in my practice

Dr J H Thompson—Individually I have not used the methyl-violet, but I have seen it used in several cases, and I have never seen it used but that most valuable time was lost I have seen it used in eyes and they would be destroyed, not from the methyl-violet but because a disease was thus allowed to run too long for any after treatment to be effective In general surgery as well as in ophthalmic practice such has been my observation, so I have come to the conclusion that the drug is useless

Dr Hotz—Observations of this kind are absolutely worthless To use a drug indiscriminately for almost every disease the eye may be afflicted with is not a scientific experiment but empiricism Methyl-violet was introduced by Prof Stilling under the name of "pyoktanin," i e , pus killer, to emphasize its most prominent quality Now if we wish to find out for ourselves whether this remedy possesses this pus-destroying power in so eminent a degree we must test its power in such suppurative affections which we know usually run a very destructive course Serpiginous ulcers of the cornea, hypopyon keratitis, gonorrheic conjunctivitis, these are conditions where pyoktanin can show its virtues if it has any My tests had the following results in suppurations of the cornea it seemed to arrest the formation of pus cells, for the hypopyon and the yellow infiltrated border line of the ulcers disappeared, but in most cases the disintegration of tissue went right on leading to extensive softening, and eventually to perforation of the cornea In one case of incipient gonorrhea of the conjunctiva pyoktanin seemed to cut short the attack, only a mild form of simple conjunctivitis followed its use But in other cases of gonorrheic ophthalmia, in all cases of blennorhea of the membrane its applications were utterly ineffective I have come to the conclusion that pyoktanin is a useless remedy But when we are told it had cured a glioma of the retina, I believe the only rational explanation we can offer is that there was a mistake in the diagnosis

Dr Tiffany—Dr Hotz in his remarks deprecates the efficiency of methyl-violet in neoplasms and all forms of tumors He says that all that is claimed for it is its value as an antiseptic We all know that this drug in our histological preparations is one of the best stains that we have, taking for its predilection the nucleus of the cell If we concede that the drug is an antiseptic a destroyer of microbes, I see no reason why it may not in a similar way control cell proliferation of tumors and neoplasms at any rate, we all know that it has been extensively used not only here in America, but in Europe, and by good authority who claimed for it the power of checking if not dissipating entirely these growths I am sure my experience will bear me out in all I have said in my paper Very recently, within the last few days, I had a case of hypopyon where the anterior chamber was filled with pus in which I used methyl-violet with excellent results, clearing the chamber in a few days In phlyctenular keratitis I have repeatedly used it with most satisfactory results I have been disappointed in its use where it was most recommended by Prof Stilling, viz in most affections of the conjunctiva I have found it most useful in the affections of the uveal tract and of different intra-ocular affections

---

QUIESCENT FOREIGN BODIES WITHIN THE EYEBALL WITH A REPORT OF CASES

Read before the Section on Ophthalmology at the Forty fourth Annual Meeting of the American Medical Association at Milwaukee

BY WALTER B JOHNSON, M D
PATERSON, N J
SURGEON TO THE PATERSON EYE AND EAR INFIRMARY

When the eyeball has been penetrated by any extraneous material the resulting injury and probable subsequent irritation and inflammation is always regarded with the utmost concern by the surgeon in attendance Even if the particle comprising the foreign body is very minute, if the impact has been sufficient to cause it to penetrate the walls of the eyeball and it has passed within the globe, it is a grave and serious condition The prognosis is nearly always unfavorable, as it may immediately become a source of severe suppurative inflammation resulting in destruction of the eye, necessitating its enucleation, or if allowed to remain may eventually result in disease of the injured eye, or possible sympathetic irritation and inflammation of the fellow eye Should a foreign body have entered the globe and only a moderate inflammation result, the question of its possibly becoming encysted and remaining quiescent, presents itself for consideration, and unless the location of the injury and the position of the foreign body should preclude the possibility of strenuous efforts resulting in a successful termination, or delay should endanger the fellow eye, all eyes should be given an opportunity to become quiet

The eye should be treated in all cases of foreign body with antiphlogistic medicines and applications, and general medications should be administered, when indicated, the object to be attained being the preservation of the eyeball even though it is almost certain that the eye will be sightless Should the possibility exist of sufficient sight being retained to render the eye of any service to the patient, the efforts to quiet it should be continued as long as there is any probability of the inflammation subsiding, for, a natural eyeball, if not unsightly or a constant menace to the fellow eye is infinitely preferable to an artificial eye which is always a source of discomfort, and even if most carefully matched and constructed, somewhat unsightly, in addition to being a constant expense to the wearer

The question of the possible after effects of a present foreign body is of importance and the many cases reported in which even very small particles of steel have, after years of quiescence, become a source of such severe irritation that the fellow eye has become diseased, or an enucleation of the eye rendered necessary, have had a tendency towards preventing protracted efforts to save eyes which seem to be too severely injured to undergo a satisfactory reparative process If a patient carrying an encysted foreign body can not at any future time be easily reached, or may pass entirely from proper observation in case of subsequent irritation, as, under such circumstances there is a decided objection to the continued presence of a foreign body in the eyeball, the desirability of efforts at its removal by operation or even, if necessary, the enucleation of the eyeball itself should be carefully considered The operation for removal of foreign bodies by the magnet has been performed in a large number of cases, it is, however, only moderately successful It is an extremely dangerous operation and so serious a procedure that it frequently induces severe suppurative inflammation and subsequent loss of an eyeball which might under more conservative treatment have been saved

The time required for an inflammation resulting from the presence of a foreign body in the eye to subside is frequently a matter of great importance, especially to a patient who has himself and others dependent upon his daily labor for their support

In such a case where the time would be too long, extending over a period of weeks and perhaps months before the eyeball would quiet, and if the eye were so severely injured that it would be sightless and there were some danger to the fellow eye, immediate enucleation would be a perfectly justifiable procedure The cases reported are presented for the purpose of illustrating the manner in which foreign bodies may enter the eyeball and become encysted in different localities, remaining perfectly quiescent and apparently no menace to the integrity of the globe, the sight of the fellow eye, and even in some cases the sight of the injured eye itself

Case 1—D F, age 30, Irish, machinist, July 12, while working at his trade was struck in the right eye by a piece of flying steel When first examined he had a severe iritic inflammation and a scar on the cornea temporal side, near the limbus The iritis responded readily to treatment by atropin and a leech The eye quieted and was perfectly comfortable There was no idea of a present foreign body and the patient was confident that there was nothing in the eye He had no discomfort, his vision was normal

September 1—Again applies for treatment stating that one week ago his right eye became red and painful and had a feeling of scratching as if something was in it, with blurring of the sight and severe headaches These symptoms had gradually increased until present time On examination severe inflammation with sub conjunctival infection, and a small black speck on the globe in the temporal region were observed, the foreign body, a small piece of steel, presenting near the limbus cornea in the supra-temporal quadrant was removed with some difficulty as it seemed to be tightly imbedded in the ocular tissues It was one-eighth of an inch in length and very thin and sharp pointed The irritation readily subsided under cold bathing and atropin, the eye became perfectly normal and the vision equally as good as that of the other eye

Case 2—J R, 44, foreign body encysted in iris, May 5, 1893, while working at his trade, machinist, a small piece of steel flew from the hammer and entered eyeball lodging in iris First saw patient Tuesday, May 9 At that time the eye was congested and there was a small white fleck on the iris below Had some pain, he could see well, ordered atropin, the pupil responded readily and the iritis gradually disappeared May 15 Has no pain and very little redness, his eye feels well, ordered him to remove bandage and wore shade glasses Atropin was discontinued and on May 22 there is no redness The pupil is coming down and the foreign body is evidently encysted being covered with a white exudate There is a very slight indentation on the edge of the pupil above the body, the vision is normal

Case 3—P W, steel in eyeball, one week before he applied for treatment while working at his trade, a machinist, a piece of steel flew and entered the right eyeball passing through the cornea and iris just below the pupillary margin and through or into the lens The steel can not be seen either by direct illumination or with the ophthalmoscope The lens is somewhat opaque and presents a glistening reflex The pupil is slightly dilated, the tension of the eyeball very slightly increased, has had slight pain, but there is no discomfort at present and no inflammatory symptoms The vision was 1-10 three weeks after the injury and on last advice had remained practically the same since time of injury until his death three months ago, never having caused him any discomfort, either in the injured or the fellow eye

Case 4—F G applied for treatment of an iritis, which he stated he thought might be the result of a foreign body which entered the eyeball twenty years before this time, he complained that he had on several occasions had attacks similar to the present inflammation, the pupil dilated considerably under atropin but was irregular On the temporal side there was an iridodialysis which could be readily illuminated, and directly behind the opening there was upon the fundus a large, white plaque about the size of a pea The vision in the eye was impaired being about 1-20 The iritis responded to treatment and the patient passed from observation still carrying the foreign body

Case 5—J F, age 47 Seventeen years ago received an injury from flying steel in the right eye, the steel passed into the globe in the ciliary region on the temporal side of the eye The sight was immediately lost and never returned There was no opacity of the lens and no spot or plaque could be seen on the fundus to indicate situation of the foreign body He has had occasional attacks of neuralgia in the right eye but never any inflammation He was myopic before the injury, but the sight of the left eye has never been affected as a result of the injury On Thursday three days ago he had a severe attack of neuralgia in the left eye which was the first he ever had in that eye On examination there was no apparent disease of that eye R V O L V = 20-100 with — 1-15 = 20 20

Case 6—W P, age 30, machinist One month before presenting himself for treatment and while engaged in turning on a power lathe, a spicula of steel flew from the tool striking him in the right eye, and as he thought falling to the floor He had no pain redness or swelling and did not notice any feeling of discomfort at any time until the third day after the injury, when he thought that his sight in the right eye was diminishing slightly, from that time until date of first visit one month after the injury there has been absolutely no symptoms present, except a continued falling off of the vision in the injured eye R V = 2-7 No improvement with glasses L V = 20 20 By ophthalmoscopic examination and direct illumination a small piece of steel about the size of a pin head is observed situated in the lens above and towards its supra-temporal border, directly in front and somewhat below this point a corneal scar indicates its point of entrance, the loss of vision is due to opacities of the lens September 15, 1884 The eye has given him no discomfort but the vision has steadily diminished until present visit when he only had perception of light The lens is entirely cataractous and milkwhite in color June, 1893, on examination R V = 20 15 with + 1 3 1-2 The lens is entirely absorbed, the fundus on ophthalmoscopic examination is seen with perfectness with + 1 4 The foreign body can not be discovered it probably having sunken down close behind the iris He never has had any discomfort of any kind and reports the eyesight in his injured eye of great service in discerning objects appearing on that side

Case 7—C A, age 44 While hunting on Oct 29, 1882, and one hour before presenting himself for treatment he received a wound in the right eye, scattering shot from the gun of a companion having struck him The shot used was bird shot No 6 It grazed the upper lid and entered the eyeball just at the limbus of the cornea leaving a small crescent shaped cut upon the globe There was a considerable hemorrhage into the anterior chamber There is but little swelling or irritation Ordered atropin and cold water bathing R V = perception of light October 30 on the day following the injury, R V = ability to count fingers at 6 degrees A new sub conjunctival hemorrhage has occurred near the wound The hemorrhage in the anterior chamber and also the sub conjunctival hemorrhage were gradually absorbed, the slight inflammation subsided and the vision improved, the patient remaining under treatment for two weeks When an ophthalmoscopic examination could be made no foreign body was located, there was a small plaque on the fundus in a direct line with the wound in the globe anterior and the possibility of the shot having passed entirely through the eye presented itself for consideration The vision was still impaired when the patient ceased his visits

July 24, 1891 Eleven years after the injury the patient was sent for and examined with the following result he was unable to say which eye was injured and stated that he could see as well with one eye as the other R V = 20 30 + 1-36 = 20 20 L V = 20 40 + 1-36 = 20 20 He has never had any discomfort since the original inflammation subsided The vision in the injured eye is better than the other eye when not using glasses The location of the foreign body is questionable, it probably having passed through the globe into the orbit behind the eyeball

Case 8—E Q, July 10, 1889, while celebrating the Fourth of July, was struck in the right eye with some powder grains, a cannon having prematurely exploded The grains of powder passed through the cornea and iris and into lens causing a traumatic cataract The eye was still inflamed on July 10 when first seen, it quieted nicely under treatment and by August 2 was perfectly comfortable, although the corneal wound was still open at times and there was an occasional escape of aqueous The lens remained cataractous the wound of cornea closed and the vision was only perception of light There has been no subsequent discomfort May, 1892, when last seen the eye remains sightless

Case 9—J McD, Oct 24, 1887, was struck while working as a laborer in blasting rock, by a piece of steel from a drill, the steel passed through the cornea and sclerotic at the limbus, a well marked inflammation developed with suppurative choroiditis Enucleation was advised, but the patient declined to have the eye removed, after remaining in the hospital five weeks the pain and inflammation had entirely disappeared There was tension of the eyeball and apparently an oncoming phthisis bulbi, there was only perception of light On ophthalmoscopic examination the field presented a semi-organized exudation filling nearly the entire half of the vitreous, evidently the seat of the foreign body, the exudate on last examination still had a reddish tinge resulting from the blood coloring matter not yet absorbed, the eyeball is quiet and comfortable and there is no irritability of the fellow eye The steel can not be seen, being probably concealed in the exudate mentioned above

Case 10—July, 1888, W M, was engaged in firing a cannon on the Fourth of July, the concussion of the ramrod exploded the charge of powder prematurely, he was standing in front of the cannon and the charge shot into his face, filling both eyes with powder and pieces of grass and weeds which he was using as wadding, both eyes were injured and there were dozens of particles of powder and stubs of grass and weeds removed from them The orbital cavity was literally full of such particles, which were lodged in the conjunctiva His left eyeball was severely lacerated, and the right cornea had perforating wounds through which cannon powder had passed The resulting inflammation was so severe that the enucleation of the right ball seemed absolutely necessary, the possibility of saving the left eyeball seemed very slight Under active antiphlogistic treatment the inflammation gradually subsided, there was no light in either eye at first, but ten days after the injury he was able to count fingers with the left eye No sight in right eye which was diminished in tension Present condition, June 1, 1893, phthisis bulbi of the right eye which is considerably sunken and has cicatricial contractions He never had any pain since the original inflammation subsided The left eye has a large symblepharon on the temporal side and is discolored by powder stains, the cornea is clear showing two scars where grains of powder, which are lodged in the iris entered, the pupil is mobile, there are some opacities on the anterior capsule of the lens There is a long narrow choroidal plaque extending from the temporal side of the optic nerve to the extreme limit of the field, undoubtedly due to rupture of the choroid from the force of the blow R V = 0 L V = 20 200, no improvement with glasses He has a sensation of light in the left eye which constantly flitters before the eye either night or day, seen even when the eyes are closed He describes the light as a black center surrounded by moving light, no doubt due to the blind spot in the field of vision caused by the plaque at the seat of the choroidal rupture He was at first troubled with rainbow light flashes, which would circle around and then burst, but as time passed he sees less of these, he thinks his eye is stronger than it was He has no dizziness such as he constantly had for two years after the injury No intolerance of light except in the early morning after working all night, he is employed as a night watchman and has been since the time of the injury

Case 11—July, 1889, W V S, while celebrating the Fourth of July was shot in the eye, the powder passing into the eyeball, penetrating the lens and causing a traumatic cataract, he had a severe iritic inflammation which finally subsided and the eye became comfortable but remained sightless for six weeks after the operation, when he ceased his visits He never, as requested, came back for future examination

Case 12—July, 1892, P H, while celebrating the Fourth of July was shot in the face, a small cannon loaded with blasting powder having prematurely discharged, two grains entered the eyeball and lodged in the lens passing through the cornea and iris The eyeball was excessively inflamed and the pupil contracted, the lens cataractous and a considerable deposit of plastic materal in the field of the pupil The inflammation subsided after six weeks of treatment and he was discharged with a fairly comfortable eye, his vision was only perception of light He passed from under observation never returning for examination

Case 13—W C, while celebrating the Fourth of July a cannon loaded with blasting powder was discharged by a companion and the powder entered the left side of face and eyeball, passing into the chamber of the vitreous At first there was but slight irritation and the vision was 2-5, the grains of powder which could be seen on ophthalmoscopic examination gradually assumed a yellowish cast and increased in size until as large as a mustard seed, they presented a peculiar fuzzy appearance on either direct or oblique illumination The vision was reduced to fingers at eight feet, the inflammation finally subsided, and one month after the injury the vision was ½ There was no further pain or irritation

Case 14—I E, while at work in shop was struck in the eye with a flying piece of steel which entered the eyeball and lodged in the fundus causing a number of hemorrhages, forming a large stellate hemorrhagic spot on the retina He could see one week after the operation to count fingers at twenty feet He was under observation for three weeks his eye having quieted, he was discharged His vision was ¼ He never returned to report the subsequent condition of the eyeball

Case 15—C B, a machinist, while striking a chisel a piece piece of steel flew from the head of his hammer and penetrated the eyeball, passing through the cornea, iris and lens, and lodging in the fundus at a point directly opposite its point of entrance There was considerable resulting hemorrhage into the vitreous and some hemorrhagic spots on the choroid to indicate the point of impact of the foreign body, which could not be positively demonstrated by ophthalmoscopic examination There were no opacities of the lens, although the foreign body had passed directly through it On examination on the day of the injury there was considerable loss of vision, the point of entrance and the course of the body could be demonstrated, the eye pained but little, was slightly red and the pupil did not respond readily to light, the blood in the vitreous somewhat obscured the point of lodgment in the fundus The pupil dilated readily, the inflammation quieted and there was very little discomfort during the two weeks which he remained in the hospital June 2, 1893 Has recently had some neuralgic pain in the injured eye, which has gradually grown blind and he can not on this date see anything but shadows The ophthalmoscopic examination shows the pupil slightly dilated and regular An extensive retinal detachment around the point where the foreign body had lodged, a line of opacity through lens indicating the course of the foreign body The pain in the eye and the complete loss of vision has occurred during the last three weeks, the eye having been comfortable previous to this date Enucleation was advised The vision in the left eye is 20 15, but he states that he has difficulty in locating objects and thinks he can not see as well as he could with the left eye before three weeks ago when the pain and loss of vision occurred in the injured eye

---

THE RESULTS OF THE USE OF THE ELECTRO-MAGNET FOR THE EXTRACTION OF FOREIGN BODIES FROM THE EYE, WITH A REPORT OF TEN CASES

Read in the Section on Ophthalmology at the Forty fourth Annual Meeting of the American Medical Association

BY C BARCK, M D

ST LOUIS

In the history of the use of the magnet on the eye we can distinguish two phases 1, the use of the common magnet, 2, of the electro-magnet The first one dates back as far as two hundred and fifty years ago, when Dr Fabry of Cologne, used a magnet to remove a piece of iron from the superficial layers of the cornea In 1842 Dr Meyer from Minden (Germany), used a magnet, carrying thirty-two pounds, to remove a piece of steel out of the interior through the scleral wound The first one who made a section through the sclera in order to remove a piece of steel with a magnet from the vitreous was Dr McKeown of Belfast in 1874 In 1875 Hirschberg of Berlin, made a similar trial without result These are the instances of the use of the common magnet we find in literature

The second phase begins with the construction and introduction of the electro-magnet by Hirschberg in 1879 Since this time its use has become universal and the literature on the subject quite extensive In the instrument made by McIntosh, although more neat than the ones I have seen abroad, I found it necessary to have the points made somewhat longer The battery must be powerful enough to enable the magnet to carry at least half a pound, and lately even a much stronger current has been recommended

The cases in which the use of the electro-magnet is indicated, can be divided in two categories according to the location of the foreign body in front or behind the posterior lens-capsule Those of the first, comprising the minority of the cases, are and have been within our reach by the ordinary methods, removal with forceps or other instruments, iridectomy, extraction of the traumatic cataract enclosing the body But the extraction with the electro-magnet is easier, more rapid and we can for instance remove foreign bodies situated upon or in the iris without mutilating this organ

All the cases where the foreign body penetrated beyond the posterior lens-capsule, were formerly considered beyond the scope of conservative treatment This is the special sphere of the electro magnet For the scleral incision I used at first Graefe's knife but prefer now a Beer's knife, which makes at once a section of the proper length I thrust it directly through conjunctiva and sclera in the direction of the supposed location of the foreign body, making a kind of pathway in the vitreous too The selection of the point of incision depends entirely on the calculated seat, on the determination of which I shall dwell later The external muscles must of course be avoided The loss of vitreous is exceedingly small, if there is no improper manipulation, frequently none at all Hirschberg recommends chloroform-narcosis I have operated in a number of instances under cocain and find it just as expedient as for cataract extraction, children excepted

The results are divided by Hirschberg into

1, Good results, with maintenance of good vision, 2, moderate results, some vision being saved, 3, preservation of the eyeball, 4, failures

The result depends upon

1, The size and weight of the foreign body, 2, its septic or aseptic condition, 3, the correct diagnosis as to the location

Ad 1—The foreign body can be called small when its weight is below 30 mgrs Here the removal even quite a time after the injury might be crowned with a good result If of medium size, weighing between 30 and 150 mgrs, then a primary operation only, within the first twenty-four hours will be successful If the weight of the entering body exceeds 150 mgrs, the damage done to the structures of the eye will be too extensive to save some vision, sometimes even the preservation of the eyeball is impossible

Ad 2—If the foreign body has been septic, suppuration of the vitreous sets in within twenty-four to seventy-two hours after the injury and the operation can then of course not prevent the loss of the eye The possibility of such a condition is an indication to operate as early as possible

Ad 3—The diagnosis must ascertain the presence of a metallic body in the vitreous and furthermore if possible its location This depends mainly on the transparency of the media, especially of the lens and this again on the time which has elapsed since the injury In the rarer instances where the foreign body enters through the sclera so far equatorial as not to injure the lens, it is of course less important As long as the media are clear, we can diagnose after dilatation of the pupil, the foreign body and its seat with the ophthalmoscope

A precise idea of the situation is most important The advice to operate under guidance of the ophthalmoscope is correct theoretically but deficient practically I had a small mirror made to fit into the head band for the otoscopic reflector but abandoned its use In the calculation of the seat first the meridian is determined Then the distance from the corneal margin is measured upon the basis first, that the most extreme point of the fundus, we can see, is about 8 mm distant from it, second, that every optic disc diameter corresponds to 1½ mm Furthermore an examination with the perimeter serves to control the calculation The scotoma, caused by the presence of the foreign body, is transferred to the retina according to the measurements laid down by Donders in Graefe's Archives (Vol xxiii, 2, pp 255)

It is different, if we see the cases for the first time some days after the injury when the lens has become more or less opaque In moderate degrees we might still discern the deeper seated opacity, extravasation of blood or metallic reflex After the lens has become totally cataractous this is impossible and our judgment of the probable seat rests then upon the anamnesis and especially the direction of the successive wounds in the cornea, iris, anterior and posterior lens capsule The best results are obtained in cases which are operated upon within the first twenty-four hours Moderate results are due partly to the injury done to the retina and choroid, especially where the foreign body happened to strike the region of the macula lutea, partly to opacities of the vitreous Too much fishing in the vitreous with the magnet is always detrimental to the sight, causing shrinking of the vitreous and detachment of the retina They are the cases of the third class, where the eyeball only is preserved But even this result is a gain as many people regard the loss of an eyeball as a serious mutilation

The failures are due to

1, Too large a size of the entering body, 2, a septic condition of it, 3, the impossibility to remove the foreign body because the magnet did not find it or because it was too firmly imbedded in the walls of the fundus

Eyes where operations in the vitreous have been performed should be kept under a close and long observation Hirschberg rightly insists that no statement as to the final result ought to be accepted until at least one year after the operation has elapsed I, therefore, report only my first ten cases, omitting three occurring during the last year In two the foreign body was located in the anterior half of the eyeball

Case 1—M B, 22 years old Injured two days previously In the left eye a fine scar in the cornea below and somewhat in the pupillary area In the outer inferior quadrant of the iris, near to the pupillary margin, a small metallic body could be clearly recognized by focal illumination It was imbedded in the tissue, a small portion of it projecting Pupil irregularly contracted Under cocain, corneal section downward and outward The introduced magnet attracts the piece at once and brings it forth After atropinization, the anterior lens capsule was found intact Normal healing with a round movable pupil Vision 20 30, owing to the cicatrix involving the pupil Without the magnet this case would most probably have required an iridectomy

Case 2—L O 41 years old Injury same morning Right eye Corneal cicatrix two lines long outward Corresponding perforation visible in the iris One-third of anterior chamber filled with blood After repeated use of atropin during two hours, pupil sufficiently dilated A black dimly reflecting foreign body could be diagnosticated in the outer half of the crystalline lens Expectative treatment during three weeks, after which time the lens was sufficiently opaque Iridectomy upward and outward The piece of steel follows easily the introduced magnet Removal of the cataract as usual Normal healing Secondary cataract operation later Final result, vision 20 70 with + 11 0D In this case, the same result could have been attained by the ordinary method The use of the magnet seemed to me of advantage

In the other cases the foreign body entered the vitreous chamber I shall give them in chronological order

Case 3—L M, 30 years old While striking the back of a hatchet with a hammer, the day before, a piece struck his right eye Pain in the night Eye moderately injected In the upper outer quadrant of the cornea a linear cicatrix one half line long After atropinization, a corresponding wound in anterior lens capsule near the æquator was seen The ophthalmoscope reveals, if the patient looks down, a roundish opacity in the vitreous with a metallic reflex from its center, apparently not far behind the posterior lens capsule Fundus otherwise clear Operation same day under cocain Scleral section between superior and external rectus On the third introduction of the magnet it brought forth a minute piece of iron No loss of vitreous Conjunctival suture Healing process normal without pain and very little irritation Vitreous at first cloudy, then clearing up Traumatic cataract did not follow Dismissed the 15th of December No injection of eyeball Vision = 20 40 On the place of the foreign body an irregular opacity of vitreous with corresponding narrowing of the visual field Status the same two years later

Case 4—Young man from the country, seen in consultation with Dr Williams of St Louis Chip of iron had entered the eye two weeks previously Traumatic cataract Fundus not visible Scleral section between inferior and external rectus The foreign body could not be found with the magnet The eye was afterwards enucleated by Dr Hotz of Chicago

Case 5—L S, 27 years Injury three hours previously while working on the rim of a barrel Right eye In the inner lower quadrant of the cornea a closed wound one line long In the same direction in the iris an oblong perforation reaching close to the pupillary margin Pupil dilated after one and a half hours Wound in anterior as well as in posterior capsule and the way of the foreign body through the lens in form of an opaque streak clearly visible In the vitreous near to the retina a gray-yellowish, sharp circumscribed opacity the size of the optic disc From the center, a metallic reflex Operation same morning in narcosis Incision with a Graefe's knife in inner lower quadrant 3mm long On the second introduction of the magnet the metallic body springs to it with a loud click and is easily extracted Weight, 15 mgrs Healing of the wound regular The development of the traumatic cataract caused for a time glaucomatous symptoms After its resorption the eye was found blind in consequence of detachment of the retina

Case 6—Young man, seen November 1889 Injury three days previously Corneal wound Lens nearly totally opaque so that nothing of the fundus could be seen In the grayish lens substance there is a sharply circumscribed black spot which looks like a foreign body On the ground of the possibility of this location the section was made in the cornea The introduced magnet proved the fallacy of this supposition and it was then introduced deeper through the lens into the vitreous The foreign body could not be found The patient did not return, and I do not know what became of him The eye must of course be counted as lost

I would like to mention here that a small oblong transparent portion in an otherwise opaque lens looks just like a foreign body, and is highly deceiving The only difference is the presence or want of a metallic reflex If this is wanting the location of the foreign body should always be supposed to be in the vitreous chamber and the scleral section ought to be made

Case 7—O R, 40 years old Right eye received injury seven days ago Horizontal scar in upper inner quadrant of the cornea one and a half line long Behind it, perforation of the iris Lens nearly completely opaque, but the wound canal from anterior to posterior lens capsule and in a downward direction plainly visible Farther back in the vitreous there is a dark spot with slightly metallic reflex just perceptible Location of it impossible Operation the next day under cocain Owing to external circumstances I decided to remove in the same operation the cataract and entered therefore with the magnet, after a corneal section downward and extraction of the cataract through the pupil I proceeded the same way in Case 9 But although the result in this case was favorable I can not recommend the procedure It is much more difficult to manipulate with the magnet from a corneal than from a scleral incision, and the extraction of the cataract ought to be left to a subsequent operation The foreign body was found after some searching on the bottom of the vitreous and removed Weight, 10 mgrs The healing process was a regular one with very slight symptoms of irritation A discission of the capsular cataract on March 1 1891, produced a round pupil in the center Fundus clear, only fine opacities in vitreous Vision = 20 40 with + 12 0D Reads Snellen III with + 15 0 This status has been the same up to date As the other eye of the patient had been considerably injured by a previous accident (vision only 20 200), this one enabled him since to do his work and earn his living

Case 8—R L, aged 28 Injury received six weeks previously in the country A large piece of iron from a chisel had entered the eye Large cicatrix at cornea-scleral margin Traumatic cataract Iris dull and discolored Chemosis Swelling of the upper lid The other eye injected, pronounced photophobia As the patient was very anxious to have his eye saved, a last resort was made in spite of the symptoms of commencing sympathetic affection of the other eye Scleral section From the vitreous there was attracted at once a large piece of iron, necessitating enlargement of the wound in order to remove it Weight 630 mgrs There was some pus on its surface On that account, and as the sympathetic symptoms rather increased, the shrunken eye was removed two days later Under appropriate treatment the other eye recovered fully

Case 9—J P, 52 years old Piece of steel from a chisel entered the eye five days previously Large irregular horizontal cicatrix in cornea not fully closed as yet Anterior chamber shallow Pupil dilates only partially from atropin Lens opaque Place on laceration in anterior and posterior capsule recognizable, no reflex from fundus The foreign body had most probably caused a considerable hemorrhage I deemed it best in this case to proceed as in Case 7, especially as the corneal wound had not united fully I, therefore, reopened and enlarged it, removed the opaque lens masses, and entered with the magnet through the pupil In spite of long searching the foreign body could not be found The patient disappeared a few days afterwards

Case 10—J D, 14 years old A piece of steel from a plate, crushed by a large hammer, struck the right eye Seen immediately after the injury Corneal cicatrix in outer lower quadrant Triangular wound in iris, which is slightly adherent to the cicatrix After atropinization, wound in anterior and posterior lens capsule visible Ophthalmoscope reveals at the bottom of the vitreous an opacity with metallic reflex Fundus otherwise clear Operation three hours after injury in narcosis Scleral section between inferior and external rectus The click on touching the foreign body was heard twice, but it followed the third introduction only, having probably been firmly sticking in the sclera with its very sharp end Weight 10 mgrs Loss of one drop of vitreous Conjunctival suture Healing process normal Traumatic cataract left to absorption Discission August 1892 Vitreous considerably cloudy, especially in lower portion, and most probably retinal and choroidal atrophy Counts fingers at 1½ meter distance Status about the same now It is doubtful if this moderate amount of vision will not become lost in the future

The eight cases of extraction from the vitreous give the following results

Two, good ones 1, moderate one, 1, preservation of the eyeball, 4, failures

The most extensive experience on this subject is possessed by Hirschberg, who reported (Graefe's Archives, 1890) a series of 100 consecutive cases from 1879–90 Among them in forty-one, the foreign body was situated in the vitreous chamber and his results were

Four, good ones, 3, moderate ones, 6, preservations of the eyeball, 28, failures.

His failures were in a large percentage of the cases due to septic infection already existing at the time of the operation.

Another large collection of cases has been reported by Mayweg (Archives of Ophth., xxiii, p. 278). In fifty out of sixty-six the seat was in the vitreous chamber. His results were:

Nine, good ones, 7, moderate ones, 6, preservations of the eyeball, 22, failures.

In six the final result unknown. From the literature at my command, I could collect up to 1892 258 cases, including the above mentioned series. The results of these were:

Fifty-eight, good ones; 40, moderate ones, 37, preservations of the eyeball, 123, failures.

The pronounced difference between these statistical results and those of Hirschberg is striking, but easily to be accounted for. These cases have been reported by numerous different authors, one or a few at the time and many of them beyond doubt too early. Furthermore, good results are published, as in surgery generally, failures passed over in silence. Therefore but little value can be attached to such collected statistics, and in my opinion only a larger number by one operator, or series of such, can form the proper basis to guide us. If the results so far have not been brilliant they have nevertheless been encouraging and they will undoubtedly become better with our increased experience.

DR. J. L. THOMPSON—The first paper was a very valuable one on the use of the electro magnet for the purpose of extracting foreign bodies from the vitreous. As to the second one, concerning quiescent bodies, we should like to have heard the last of that paper; without that we can say very little about it. Patients should be repeatedly warned by their physicians as to the danger of these foreign bodies. Tell them of the danger of the foreign body setting up inflammation many years afterwards. In such cases I have always given Solon's advice to Crœsus: "Count no man happy until he is dead." There are some physicians who let the poor creatures go on with the injuries telling them: "Well, there is not much danger," until the patient goes on and loses the other eye. If the doctor had told him of the danger he would have been more practical and saved his eye.

DR. BAKER—I had the pleasure in 1882 of spending some months with Prof. Hirschberg in Berlin and seeing him make several attempts at extraction of foreign bodies from the eyeball with an electro-magnet. On my return home in 1883 I had a magnet made, an improvement on his, in that it would lift five or six pounds while his would lift only ten or fifteen ounces. We have in Cleveland, as in all manufacturing centers, a number of penetrating wounds of the eyeball. It is always a difficult problem to know how to treat these cases, and the electro magnet has been of much value to me in making a diagnosis. In a few cases it has proved of great service in the removal of fragments of iron or steel from the interior of the eyeball.

I recall one case referred to me by the late Dr. Weed in which he supposed the injury was only conjunctival and put a stitch in it; there was hemorrhage in the anterior chamber which obstructed the view with the ophthalmoscope. As soon as I brought the electro-magnet near the eyeball I knew there was a foreign body in it by the way in which the ball followed the magnet, and the pain complained of by the patient. I opened the wound and by the aid of the magnet soon found and removed the piece of steel, which was about the size of my little finger nail. The man is still carrying the eye without any vision, but it looks as well as the other. In another case I could see a piece of something, not much larger than a pin head, very distinctly in the center of the vitreous. I made an opening in the chamber opposite and inserted my magnet repeatedly. I could hear the click of the instrument against the foreign body but it would not come out. I kept this up for a long time but could not get it. After consulting with the patient we decided the eye must come out. I enucleated the eye and upon opening it took the magnet and placed it in contact with the foreign body but could not extricate it. I could lift the entire eyeball with this piece of steel adhering to the magnet, and yet it would not separate from the vitreous. The inflammatory capsule held this piece of steel there. Could I have permitted that foreign body to remain without harm? I had another case not very long ago who had a piece of steel in his eye eight years; after that long time of quiescence it set up sympathetic inflammation and caused the loss of the fellow eye. I do not like the term, "quiescent foreign bodies in the eye." I do not think it best to convey the idea to the mind of the general practitioner that he can safely leave these foreign bodies in the eye. It might do if we could have them under our own control, but it is not well for us to let patients go from under our care with these foreign bodies in their eyes.

DR. MURRELL—I had occasion to present a paper last year on the subject of sympathetic troubles and how to deal with them. In reference to the first paper I will say that my experience with the electro magnet has not been satisfactory. I have tried it in a few instances and have always failed to save the eye. The foreign body is usually tangled up in the fibers of the vitreous. I have had two or three typical cases and in each have failed and had to remove the eye afterwards. In reference to quiescent bodies in the eye, I think it is a very dangerous thing to leave them in position. Of course, we know that injuries in uveal tract are most liable to give rise to sympathetic trouble, but even in the vitreous humor there is danger of sympathetic trouble following if the foreign body can not be removed from the eye. I have seen a number of cases where foreign bodies have been carried a number of years and then have sympathetic inflammation set up in the other eye. I treated an eye with a piece of glass in it that had been carried for ten years. The piece of glass measured more than half an inch and had very sharp edges, sharp enough to cut. It had cut transversely through the cornea into the sclera about four millimeters on either side. It was evidently in the ciliary body, yet it was carried ten years without the slightest trouble. However, I advised the removal of the eye because the patient was blind and as a safeguard. On opening the eye I found the piece of glass. As Dr. Thompson has said, the patient was better without the eye, in his judgment, than to run the risk of carrying it.

DR. JACKSON—The case reported by Dr. Baker in this discussion brings out a feature I do not remember to have seen mentioned, as to the use of the magnet in extracting foreign bodies from the vitreous. A foreign body can be dragged through the vitreous with very great difficulty or not at all by the magnet, unless you drag it through the wound of entrance. In one case I saw the patient thirty-six hours after the foreign body (quite a small particle of steel) entered the eye. The wound of entrance being small and the foreign body lodged on the other side of the eye a wound was made at the outer side of the vitreous chamber. Inserting the magnet, which was working well, it was tried repeatedly to drag the body out. The instrument would come in contact with the foreign body but it was impossible to dislodge it. So in Dr. Baker's case he tells me he had chamber filled with blood After repeated use of atropin during two hours, pupil sufficiently dilated A black dimly reflecting foreign body could be diagnosticated in the outer half of the crystalline lens Expectative treatment during three weeks, after which time the lens was sufficiently opaque Iridectomy upward and outward The piece of steel follows easily the introduced magnet Removal of the cataract as usual Normal healing Secondary cataract operation later Final result, vision 20-70 with + 11 OD In this case, the same result could have been attained by the ordinary method The use of the magnet seemed to me of advantage

In the other cases the foreign body entered the vitreous chamber I shall give them in chronological order

Case 3—L M, 30 years old While striking the back of a hatchet with a hammer, the day before, a piece struck his right eye Pain in the night Eye moderately injected In the upper outer quadrant of the cornea a linear cicatrix one-half line long After atropinization, a corresponding wound in anterior lens capsule near the æquator was seen The ophthalmoscope reveals, if the patient looks down, a roundish opacity in the vitreous with a metallic reflex from its center, apparently not far behind the posterior lens capsule Fundus otherwise clear Operation same day under cocain Scleral section between superior and external rectus On the third introduction of the magnet it brought forth a minute piece of iron No loss of vitreous Conjunctival suture Healing process normal without pain and very little irritation Vitreous at first cloudy, then clearing up Traumatic cataract did not follow Dismissed the 15th of December No injection of eyeball Vision = 20 40 On the place of the foreign body an irregular opacity of vitreous with corresponding narrowing of the visual field Status the same two years later

Case 4—Young man from the country, seen in consultation with Dr Williams of St Louis Chip of iron had entered the eye two weeks previously Traumatic cataract Fundus not visible Scleral section between inferior and external rectus The foreign body could not be found with the magnet The eye was afterwards enucleated by Dr Hotz of Chicago

Case 5—L S, 27 years Injury three hours previously while working on the rim of a barrel Right eye In the inner lower quadrant of the cornea a closed wound one line long In the same direction in the iris an oblong perforation reaching close to the pupillary margin Pupil dilated after one and a half hours Wound in anterior as well as in posterior capsule and the way of the foreign body through the lens in form of an opaque streak clearly visible In the vitreous near to the retina a gray-yellowish, sharp circumscribed opacity, the size of the optic disc From the center, a metallic reflex Operation same morning in narcosis Incision with a Graefe's knife in inner lower quadrant 3mm long On the second introduction of the magnet the metallic body springs to it with a loud click and is easily extracted Weight, 15 mgrs Healing of the wound regular The development of the traumatic cataract caused for a time glaucomatous symptoms After its resorption the eye was found blind in consequence of detachment of the retina

Case 6—Young man, seen November 1889 Injury three days previously Corneal wound Lens nearly totally opaque so that nothing of the fundus could be seen In the grayish lens substance there is a sharply circumscribed black spot which looks like a foreign body On the ground of the possibility of this location the section was made in the cornea The introduced magnet proved the fallacy of this supposition and it was then introduced deeper through the lens into the vitreous The foreign body could not be found The patient did not return, and I do not know what became of him The eye must of course be counted as lost

I would like to mention here that a small oblong transparent portion in an otherwise opaque lens looks just like a foreign body, and is highly deceiving The only difference is the presence or want of a metallic reflex If this is wanting the location of the foreign body should always be supposed to be in the vitreous chamber and the scleral section ought to be made

Case 7—O R, 40 years old Right eye received injury seven days ago Horizontal scar in upper inner quadrant of the cornea one and a half line long Behind it, perforation of the iris Lens nearly completely opaque, but the wound canal from anterior to posterior lens capsule and in a downward direction plainly visible Farther back in the vitreous there is a dark spot with slightly metallic reflex just perceptible Location of it impossible Operation the next day under cocain Owing to external circumstances I decided to remove in the same operation the cataract and entered therefore with the magnet, after a corneal section downward and extraction of the cataract through the pupil I proceeded the same way in Case 9 But although the result in this case was favorable I can not recommend the procedure It is much more difficult to manipulate with the magnet from a corneal than from a scleral incision, and the extraction of the cataract ought to be left to a subsequent operation The foreign body was found after some searching on the bottom of the vitreous and removed Weight, 10 mgrs The healing process was a regular one with very slight symptoms of irritation A discission of the capsular cataract on March 1 1891, produced a round pupil in the center Fundus clear, only fine opacities in vitreous Vision = 20 40 with + 12 OD Reads Snellen III with + 15 0 This status has been the same up to date As the other eye of the patient had been considerably injured by a previous accident (vision only 20 200), this one enabled him since to do his work and earn his living

Case 8—R L, aged 28 Injury received six weeks previously in the country A large piece of iron from a chisel had entered the eye Large cicatrix at cornea-scleral margin Traumatic cataract Iris dull and discolored Chemosis Swelling of the upper lid The other eye injected, pronounced photophobia As the patient was very anxious to have his eye saved, a last resort was made in spite of the symptoms of commencing sympathetic affection of the other eye Scleral section From the vitreous there was attracted at once a large piece of iron, necessitating enlargement of the wound in order to remove it Weight 630 mgrs There was some pus on its surface On that account, and as the sympathetic symptoms rather increased, the shrunken eye was removed two days later Under appropriate treatment the other eye recovered fully

Case 9—J P, 52 years old Piece of steel from a chisel entered the eye five days previously Large irregular horizontal cicatrix in cornea not fully closed as yet Anterior chamber shallow Pupil dilates only partially from atropin Lens opaque Place on laceration in anterior and posterior capsule recognizable, no reflex from fundus The foreign body had most probably caused a considerable hemorrhage I deemed it best in this case to proceed as in Case 7, especially as the corneal wound had not united fully I, therefore, reopened and enlarged it, removed the opaque lens masses, and entered with the magnet through the pupil In spite of long searching the foreign body could not be found The patient disappeared a few days afterwards

Case 10—J D, 14 years old A piece of steel from a plate, crushed by a large hammer, struck the right eye Seen immediately after the injury Corneal cicatrix in outer lower quadrant Triangular wound in iris, which is slightly adherent to the cicatrix After atropinization, wound in anterior and posterior lens capsule visible Ophthalmoscope reveals at the bottom of the vitreous an opacity with metallic reflex Fundus otherwise clear Operation three hours after injury in narcosis Scleral section between inferior and external rectus The click on touching the foreign body was heard twice, but it followed the third introduction only, having probably been firmly sticking in the sclera with its very sharp end Weight 10 mgrs Loss of one drop of vitreous Conjunctival suture Healing process normal Traumatic cataract left to absorption Discission August, 1892 Vitreous considerably cloudy, especially in lower portion, and most probably retinal and choroidal atrophy Counts fingers at 1½ meter distance Status about the same now It is doubtful if this moderate amount of vision will not become lost in the future

The eight cases of extraction from the vitreous give the following results

Two, good ones 1, moderate one, 1, preservation of the eyeball, 4, failures

The most extensive experience on this subject is possessed by Hirschberg, who reported (Graefe's Archives, 1890) a series of 100 consecutive cases from 1879–90 Among them in forty-one, the foreign body was situated in the vitreous chamber and his results were

Four, good ones, 3, moderate ones, 6, preservations of the eyeball, 28, failures

His failures were in a large percentage of the cases due to septic infection already existing at the time of the operation

Another large collection of cases has been reported by Mayweg (Archives of Ophth, xxiii, p 278) In fifty out of sixty-six the seat was in the vitreous chamber His results were

Nine, good ones, 7, moderate ones, 6, preservations of the eyeball, 22, failures

In six the final result unknown From the literature at my command, I could collect up to 1892 258 cases, including the above mentioned series The results of these were

Fifty-eight, good ones 40, moderate ones, 37, preservations of the eyeball, 123, failures

The pronounced difference between these statistical results and those of Hirschberg is striking, but easily to be accounted for These cases have been reported by numerous different authors, one or a few at the time and many of them beyond doubt too early Furthermore, good results are published, as in surgery generally, failures passed over in silence Therefore but little value can be attached to such collected statistics, and in my opinion only a larger number by one operator, or series of such, can form the proper basis to guide us If the results so far have not been brilliant they have nevertheless been encouraging and they will undoubtedly become better with our increased experience

Dr J L Thompson—The first paper was a very valuable one on the use of the electro magnet for the purpose of extracting foreign bodies from the vitreous As to the second one, concerning quiescent bodies, we should like to have heard the last of that paper, without that we can say very little about it Patients should be repeatedly warned by their physicians as to the danger of these foreign bodies Tell them of the danger of the foreign body setting up inflammation many years afterwards In such cases I have always given Solon's advice to Crœsus "Count no man happy until he is dead" There are some physicians who let the poor creatures go on with the injuries telling them "Well, there is not much danger," until the patient goes on and loses the other eye If the doctor had told him of the danger he would have been more practical and saved his eye

Dr Baker— I had the pleasure in 1882 of spending some months with Prof Hirschberg in Berlin and seeing him make several attempts at extraction of foreign bodies from the eyeball with an electro-magnet On my return home in 1883 I had a magnet made, an improvement on his, in that it would lift five or six pounds while his would lift only ten or fifteen ounces We have in Cleveland, as in all manufacturing centers, a number of penetrating wounds of the eyeball It is always a difficult problem to know how to treat these cases, and the electro magnet has been of much value to me in making a diagnosis In a few cases it has proved of great service in the removal of fragments of iron or steel from the interior of the eyeball

I recall one case referred to me by the late Dr Weed in which he supposed the injury was only conjunctival and put a stitch in it, there was hemorrhage in the anterior chamber which obstructed the view with the ophthalmoscope As soon as I brought the electro-magnet near the eyeball I knew there was a foreign body in it by the way in which the ball followed the magnet, and the pain complained of by the patient I opened the wound and by the aid of the magnet soon found and removed the piece of steel, which was about the size of my little finger nail The man is still carrying the eye without any vision, but it looks as well as the other In another case I could see a piece of something, not much larger than a pin head, very distinctly in the center of the vitreous I made an opening in the chamber opposite and inserted my magnet repeatedly I could hear the click of the instrument against the foreign body but it would not come out I kept this up for a long time but could not get it After consulting with the patient we decided the eye must come out I enucleated the eye and upon opening it took the magnet and placed it in contact with the foreign body but could not extricate it I could lift the entire eyeball with this piece of steel adhering to the magnet, and yet it would not separate from the vitreous The inflammatory capsule held this piece of steel there Could I have permitted that foreign body to remain without harm? I had another case not very long ago who had a piece of steel in his eye eight years, after that long time of quiescence it set up sympathetic inflammation and caused the loss of the fellow eye I do not like the term, "quiescent foreign bodies in the eye" I do not think it best to convey the idea to the mind of the general practitioner that he can safely leave these foreign bodies in the eye It might do if we could have them under our own control, but it is not well for us to let patients go from under our care with these foreign bodies in their eyes

Dr Murrell—I had occasion to present a paper last year on the subject of sympathetic troubles and how to deal with them In reference to the first paper I will say that my experience with the electro-magnet has not been satisfactory I have tried it in a few instances and have always failed to save the eye The foreign body is usually tangled up in the fibers of the vitreous I have had two or three typical cases and in each have failed and had to remove the eye afterwards In reference to quiescent bodies in the eye, I think it is a very dangerous thing to leave them in position Of course, we know that injuries in uveal tract are most liable to give rise to sympathetic trouble, but even in the vitreous humor there is danger of sympathetic trouble following if the foreign body can not be removed from the eye I have seen a number of cases where foreign bodies have been carried a number of years and then have sympathetic inflammation set up in the other eye I treated an eye with a piece of glass in it that had been carried for ten years The piece of glass measured more than half an inch and had very sharp edges, sharp enough to cut It had cut transversely through the cornea into the sclera about four millimeters on either side It was evidently in the ciliary body, yet it was carried ten years without the slightest trouble However, I advised the removal of the eye because the patient was blind and as a safeguard On opening the eye I found the piece of glass As Dr Thompson has said, the patient was better without the eye, in his judgment, than to run the risk of carrying it

Dr Jackson—The case reported by Dr Baker in this discussion brings out a feature I do not remember to have seen mentioned, as to the use of the magnet in extracting foreign bodies from the vitreous A foreign body can be dragged through the vitreous with very great difficulty or not at all by the magnet, unless you drag it through the wound of entrance In one case I saw the patient thirty six hours after the foreign body (quite a small particle of steel) entered the eye The wound of entrance being small and the foreign body lodged on the other side of the eye a wound was made at the outer side of the vitreous chamber Inserting the magnet, which was working well, it was tried repeatedly to drag the body out The instrument would come in contact with the foreign body but it was impossible to dislodge it So in Dr Baker's case he tells me he had made a new wound of entrance through which he introduced the magnet, and not through the wound made by the foreign body This perhaps has been more frequently the cause of failure than has been noted I think it much safer to have the foreign body out of the eye, if possible, but the large majority of these cases that do well after the magnet extraction are probably cases which might have done well had the foreign body remained in the eye

Dr Allport—In regard to the use of the electro-magnet my experience has been rather unfortunate I have upon several occasions extracted foreign bodies from the interior of the globe by the use of the magnet, but have subsequently lost the eye The intra ocular manipulation of the instrument has seemed to be more than the eye could endure I would not, however, condemn the use of the magnet Good results are reported and I may have been unskillful in the operation It should certainly be used in superficial lodgment of foreign bodies that are beyond reach by other methods But I should have to be absolutely *sure* of the presence of a foreign body inside the eyeball to make any more experimental intra-ocular searchings with an electro magnet

In regard to quiescent foreign bodies in the eye I feel convinced that there is no safety while a foreign body is in the eye, and that if its extraction is impossible the eye should be removed There are eyes that carry foreign bodies for years and thus produce a loss of both eyes It is not conservative practice to allow patients to take such chances These patients are usually laboring people of a low order of intelligence, and are apt to wander from one part of the country to the other A sympathetic inflammation is liable to occur at any time under the most adverse circumstances as to skilled surgical attendance, etc The loss of one or both eyes will be the probable result We should do our duty and advise the enucleation of an eye, when we are sure of the presence of a foreign body before the patient passes from under our observation In this connection let me advise some concerted action with regard to enforcing legislation calculated to prohibit the manufacture and sale of toy guns and pistols In the month of June I was compelled to remove no less than three eyes from children who had been playing with these mischievous playthings During the same month a medical friend of mine in Winona, Minn , was forced to mourn the loss of a young son, killed while playing with one of these dangerous instruments If our wise legislators could drop for a time the discussion of such burning subjects as the smoking of cigarettes, the draping of nude statues, the covering of similar pictures, and the wearing of hoopskirts, and direct their attention to the advisability of permitting the manufacture and sale of toy guns and pistols, they would fill a longfelt want

Dr Frothingham—I wish to discuss briefly two points that have been presented The first is a statement that has been made by a previous speaker, that if a foreign body has entered the eye and we can not remove it we should enucleate the eye at once without regard to other conditions I do not think experience warrants so 'hard and fast" a rule as that While in the great majority of cases enucleation will be necessary sooner or later, we should not decide the question of enucleation alone upon the fact that a foreign body is lodged within the eye, but upon the amount of injury and the reaction that follows, that is, upon the symptoms of an inflammatory nature in the injured eye that indicate danger to the other eye through sympathy We all know that foreign bodies may remain in the eye for years without causing any feeling of discomfort or endangering the other eye I once had a patient, an aged gentleman, who suffered from senile cataract Many years before, while he was a young man, he had a piece of steel enter the eye and lodge in the upper portion of the iris, where it had become encysted, and after a brief period of irritation had never troubled him in the least, and the vision had remained perfect until the senile cataract commenced to form As the cataract was mature in this eye I operated, and in removing the usual section of the iris I removed the foreign body also There are many instances where foreign bodies have remained in the deeper structures for many years without producing any symptoms that indicate enucleation of the injured eye I had a patient a young man, suffering with pain in a blind eye, and sympathetic irritation of the other The painful eye had been blind from childhood, but until a short time before consulting me it had caused him no discomfort There was an injury of the iris, an absence of the lens, and a small scar of the cornea which indicated that a foreign body had penetrated the eye long before He was then twenty-six years of age and said he had never received any injury of the kind The eye was enucleated and a small piece of steel was found lodged upon the inner surface of the sclerotic The patient afterwards recalled the fact that when a small boy, about six years of age, he was watching some men while they were drilling a stone, and that something struck him in the eye causing pain This was a case where a foreign body had penetrated the eye, and yet, not until about twenty years afterward did it give rise to symptoms that called for its enucleation This patient made a perfect recovery Now there are a sufficient number of similar cases on record to forbid our acceptance of a rule that we should enucleate an eye at once if a foreign body has entered it, and we can not remove that body If all symptoms of irritation speedily subside and there is no recurrence of pain or feeling of discomfort in the injured eye and the other is unaffected in any way we are justified in waiting, and under certain circumstances should wait until symptoms of pain and irritation recur in the injured eye and indicate danger to the other through sympathy We should never allow a patient to go without warning, and should fully impress him with the danger of delay after symptoms of irritation recur in the injured eye, and in all cases where the recovery from the effect of the injury is not steady, and of short duration, we should enucleate

I remember a case something like this one reported by Dr Baker the patient, a man of intelligence, had a small bit of steel penetrate his eye a few months before I saw him The vision of the eye was not greatly impaired and there was on first examination but little indication of irritation or danger to the other eye, and I thought the patient was perhaps unduly alarmed, I hesitated to sacrifice an eye that possessed so good vision until thoroughly satisfied that it was necessary Upon ophthalmoscopic examination the position of the foreign body could be plainly made out in the posterior portion of the vitreous humor, where it seemed suspended and surrounded by a thin film of semi-transparent tissue I kept the patient under observation in the hospital, and finding that there were well marked symptoms of irritation at times which prevented his use of the other eye I decided to make an attempt to remove the foreign body, and failing in this to enucleate the eye Having the patient's consent, I had him put under the influence of an anesthetic, and making the usual incision tried with a powerful magnet to extract the foreign body but without success I then enucleated the eye which I opened, with the foreign body plainly in view and the magnet brought as close as could be I was unable to move it, although there seemed but a slight change in the vitreous surrounding the metal

Dr LeMond—I do not think there is anything more in keeping with conservative ophthalmology than to enucleate the eyeball if any sympathetic irritation is present. A few days ago at my home in Denver on the day I was preparing to start for Milwaukee, a gentleman came to my office who had an injured eye. The ocular injection was very great and inflammatory action had gone to a considerable extent. The well eye I noticed, on examination, was wanting quite a little in power to accommodate. He said to me "I came to get some medicine for my eye." I examined it carefully and found that it had been caused by the introduction of a foreign body. I told him he was running a considerable risk in allowing the affected eye to remain in its orbit and assured him that he had a sympathetic irritation in the well eye, which was likely to produce total blindness unless attended to at once. The affected eye looked phthisical, was minus tension and the vision was entirely gone. I said "I will enucleate the eye for you, if you want it done, otherwise I will do nothing." He went away but soon returned and informed me that he would take my advice and have the operation performed. On opening it I found the remains of a foreign body.

About three years ago lady came to my office and said "Doctor, I have come to get something to allay this inflammation in my eye." It had never given her such trouble before. It was brought about by the introduction of a small piece of thorn having pierced the ciliary body. I told her I would enucleate the eye by all means, as she was beginning also to have sympathetic trouble in the well eye, and that I could not be honest in advising her to try to hold on to the injured eye longer, as it would be running a risk that I would not carry for a thousand dollars a day. She refused to abide by my advice and went away and the sequelæ will tell the result: in three months she returned, and I found that the injured eye had recovered, to a great extent, from the introduction of the foreign body, but on examining the other eye, alas! I found it too was in total darkness. Had I advised this woman at her first visit to me to have pursued the course she did, my conscience would haunt me to this very hour for not doing my duty. I do not say to do a wholesale enucleation for every foreign body—far from this, if sympathetic inflammation has manifested its presence I never fail to advise enucleation, and I have got the first case to regret for having taken such a course. I do not think we act wisely by attempting to carry these risks. This case is only one of a dozen or more that has come under my own observation with like results.

Dr. Hotz—called attention to the fact that prognostically it made a vast difference whether the foreign body in the eyeball was lodged in the vitreous, or in the lens, or in the iris. General statements therefore on foreign bodies in the eye without mentioning the location must be misleading; for instance, when a gentleman said it was his rule to take any eye out in which he found a foreign body, he certainly did not wish us to believe he would enucleate eyes having a foreign body in the iris or lens, for these foreign bodies may be either left in situ or can successfully be removed and the eyeball saved. But conservative treatment can not be recommended for foreign bodies in the *vitreous*. The experience of all oculists, at all times, has been that foreign bodies in the vitreous are a prolific source of sympathetic inflammation. Such eyes are a constant menace to their fellows and should be removed, for we have no right to jeopardize the sight of thousands of eyes by a conservative treatment, because in some rare exceptions it has proved satisfactory. We must not be guided in our actions by what our experience of every day shows to be the usual course with such patients.

Prof. Zehender (by invitation of the chairman) called attention to the experiments of Kries and Haab with electro magnets of unequal strength for the extraction of iron and steel from the eye without entering the eyeball, but by magnetic traction through the tunics. He has observed two cases operated on in this manner by Dr. Schloesser of Munich. In both cases the *extraction* of the iron piece succeeded very well and quite easily, but in one of these cases the piece was so big, that in spite of the extraction the eye was destroyed. He also related an instance in his experience in which he observed at the time the entrance of a foreign body into the interior of the eye in a boy, which was followed by retinal detachment and atrophy of that eyeball, but had not caused any sympathetic trouble in the fellow eye up to the time of his death sixteen years later.

THE ACTION AND SAFETY OF CHLOROFORM.

Being an abstract of a report to Surgeon Lieutenant Colonel Edward Lawrie and the Government of His Highness, the Nizam of Hyderabad, India.

BY H. A. HARE, M.D.

PROFESSOR OF THERAPEUTICS AND MATERIA MEDICA, JEFFERSON MEDICAL COLLEGE, PHILADELPHIA,

AND E. Q. THORNTON, M.D.

DEMONSTRATOR OF THERAPEUTICS.

To any one who endeavors to view the subject of chloroform anesthesia in an entirely impartial light, two objects raise themselves so high above all others that they form the peaks about which the smaller questions must cluster. The first object on which the judicial eye rests is the firm belief of many clinicians that chloroform may cause sudden cardiac death; the second object to be seen is the statement of the Hyderabad Chloroform Commissions that death from chloroform is never due to cardiac failure. In the support of the first belief we have not only wide clinical observation but also the experimental evidences of a number of investigations. In support of the second statement we have an array of experimental study, not equaled by any other research extant, associated with an enormous number of negative observations on man. Negative observations, because Lawrie alone in 25,000 cases has never had a death.

The controversy concerning the action of chloroform upon the animal organism has been waged so incessantly for many years, and has led to such extraordinary efforts for its elucidation and final decision that any one who attempts to take part finds himself swamped by the number of statements and opinions which he is forced to regard. We have, therefore, approached this research feeling it was no ordinary task, and that a path already so well traveled must be gone over with the utmost care if anything new or of value was to be discovered.

In March, 1892, Surgeon Lieut. Col. Lawrie, whose interest in this subject is recognized by the medical profession the world over, wrote to one of us (Hare) asking that another chloroform research be instituted for which the Government of his Highness the Nizam of Hyderabad would pay. The express object of the research was the reconciliation of at least some of the contradictory conclusions reached by various experimenters during the past few years.

From the immense number of observations in regard to the action of chloroform in the laboratory and in the operating room it is evident that sufficient data are at hand to give us material to reach positive conclusions, and that the contradictory results hitherto obtained must have been reached by misinterpretation and error in experimental method, tinctured perhaps by opinions formed previous to the completion of a line of study. There are certain facts in regard to chloroform which few will deny, the chief of which are that it has the advantage of rapid action without disagreeable preliminary or subsequent symptoms, its bulk is small and its odor agreeable but, more important than all, it is much more dangerous than ether.

Though the Hyderabad Commission in their preliminary conclusions (page 30, paragraph 43) assert that ether is as dangerous as chloroform if given sufficiently to produce true anesthesia, we believe that the safety of ether is so universally recognized that this conclusion of the Commission can only be excused by the remembrance that ether has probably been used as little by those who wrote this paragraph as chloroform is used in many parts of America. This possibility is made a probability when we read that "if surgeons choose to be content with a condition of semi-anesthesia, it can no doubt be produced with perfect safety, though with discomfort to the patient, by ether held rather closely over the mouth. Such a condition of imperfect anesthesia would never be accepted by any surgeon accustomed to operated under chloroform." That this statement shows, to put it mildly, that the writer knows not whereof he speaks is proved by the universal employment of ether by hundreds of the best surgeons the world over in preference to chloroform. Further than this, medical literature contains so many statistical papers showing the small percentage of deaths from ether, compared to chloroform, that this point need not be discussed.

There are certain other points in regard to the action of chloroform which may be put aside as settled and therefore not needing further study, being generally received as beyond criticism, and we have made no experiments looking to their reproduction but have devoted our efforts solely to the question over which discussion still proceeds. Thus, all investigators concur in the statement that chloroform, even in ordinary therapeutic quantity, acts as a powerful and constant depressant to arterial pressure. This conclusion has been reached by Bowditch, Minot and Coats, H. C. Wood and H. A. Hare, Gaskell and Shore, the Hyderabad Commission Nos. 1 and 2 and by every experiment in the research now carried out which forms this report. There is no evidence to the contrary and practically it has never been denied. Gaskell and Shore state, however, that chloroform may cause anesthesia without lowering blood pressure and that chloroform causes primarily a rise of pressure. They also believe that the chief cause in the fall of arterial pressure is cardiac and not vasomotor depression. The rise we have never seen except from struggles, and we have never been able to produce anesthesia without lowering the blood pressure, even when the drug was used in the smallest quantity capable of causing anesthesia and given as slowly as possible. We agree with the statement of the Hyderabad Commission that a fall of blood pressure always occurs when chloroform anesthesia is produced.

We are also forced, as the result of our studies, to differ entirely with Gaskell and Shore in their statement that the fall of arterial pressure is due primarily to a weakening of the heart's action and not to paralysis (depression?) of the vasomotor nerves. We believe that both factors cause the fall, but that the dominant factor is vasomotor depression because as will be seen in several of our tracings the pulse waves were quite strong though the blood pressure, through vasomotor relaxation, was absolutely to the abscissa line and we agree with Lawrie that no conclusions as to the action of chloroform when inhaled can be drawn from the injection experiments of Gaskell and Shore into the arteries. One of our reasons for this belief is the entire difference in result. Another reason is that any powerful drug injected into the brain will cause a rise of blood pressure. Even nitrite of amyl, the prince of vaso motor paralyzants, will do this. (See Gaskell and Shore 17, paragraph 68.) We also believe that results obtained by such interesting methods of experimentation as those employed by Gaskell and Shore are not capable of giving positively reliable information, as the conditions are so utterly at variance with those in which chloroform is given to man and, further than this, their methods are such as to give room for fallacious results which can not be excluded by the greatest caution on the part of experimenters experienced as they are.

Secondly, it is not denied by any one, that we know of that chloroform exerts a powerful, depressant, paralyzant action on the respiratory center. This is agreed to by clinicians and by every one who has experimentally studied the action of the drug on the lower animals.

Thirdly, it is universally conceded that chloroform is a lethal agent of great power when brought in direct contact with highly vitalized tissues. Aside from these facts there are a number of others in which we find ourselves strictly in accord with the conclusions of the first and second Hyderabad Commissions.

We find when the drug is pushed that insensibility comes first, then respiratory failure and finally cardiac arrest in every case in the lower animals. In other words, that cardiac arrest never ensues primarily from inhalation of chloroform.[1]

SUMMARY

From a careful study of the experiments so far reported, from studies made by one of us two years ago with H. C. Wood, and finally from this careful series of experiments we believe that the subject can be settled by the acceptance of both views in a modified form, or in other words that there is no real antagonism in the beliefs that chloroform kills by depression of the respiration or paralysis of the heart. We very positively assert that chloroform practically always kills by failure of respiration when administered by inhalation provided, and this provision is most important, that the heart of the anesthetized is healthy and has not been rendered functionally incompetent by fright or violent struggles or, again, by marked asphyxia. By a healthy heart we mean one which has not undergone true fatty degeneration or has not so severe a valvular lesion as to make the slightest variation in the even tenor of the circulation fatal.

As positively as we assert that chloroform kills primarily by respiratory failure, so do we also assert that in excessive dose by inhalation it has a depressant effect on the circulation which is chiefly due to centric vasomotor depression with final depression of the cardiac muscle itself Depression of the cardiac muscle alone is never great enough to cause death when the chloroform is given by inhalation, *but we believe that gradual asphyxia with the direct* depression of the circulation may do much towards producing a fatal result, for vasomotor integrity is *almost as necessary to life as an intact cardiac* mechanism This circulatory depression has been considered a safeguard because it was supposed to prevent chloroform going to the vital centers, but in reality it is no safeguard because profound circulatory depression is as great an evil as respiratory narcosis That the circulatory depression may be dangerous is not only evident, but it is stated to be so by the Hyderabad Commission itself at the end of paragraph No 8 This circulatory depression may be so profound that recovery is impossible, even with the most thorough artificial respiration, a fact stated by the second Hyderabad Commission in paragraph 25, which we quote in this paper This emphasizes the fact that we can not afford to totally ignore the effect of chloroform on the circulation and we can not consider the patient in danger of circulatory failure *only* when the respiration *ceases, but as soon as it becomes abnormal* On the other hand, we should remember that even if chloroform has been given properly, the arterial pressure may be so low as to give no pulse in the radial artery and yet the circulatory system be ready to respond at once when the drug is removed If, therefore, the chloroform is properly administered is there danger of its circulatory effect in man? We think that it is just at this point that our research and every other research on animals fails and necessarily fails, to produce a positive reply The variation in the action of a drug on a diseased individual from its effect on the normal one is notorious, and we have no right to dogmatically assert that there is absolutely no danger of a circulatory depression in man, even if we found no evidence of failure in dogs, because there may be many idiosyncrasies or variations through disease in the human being which may completely reverse the results of experiments on healthy animals

---

[1] Lack of space prevents the inclusion of three experimental records. They can be found in the issue of the Therapeutic Gazette for Oct. 15, 1893.

In other words, supposing that the amount of depression from very full doses of chloroform equals 25 units this amounts to little in the normal heart, but if the heart be depressed 25 additional units by disease the depression of 50 units may be fatal particularly if to this 50 is added 25 units more of depression through fright and cardiac engorgement through disordered respiration or struggling That true depression of the heart muscle may take place under chloroform seems to us most undoubted and we think that the tracings in every research that we have seen support this view There is always a decrease in cardiac power manifested by the decrease in the force of the individual pulse beat and this passes away only if chloroform is removed early enough We also agree with McWilliams that from the very first inhalation of chloroform there is a constant tendency to cardiac dilatation

We come finally to the all important questions

1 —Is chloroform a safe anesthetic?

2 —Are we to watch the pulse or respiration during the use of the drug, and what are the signs in the respiratory function indicative of danger to the patient?

3 —What is the true cause of death from chloroform?

4 —Is death from chloroform possible when it is properly administered?

5 —Under what circumstances is the surgeon to use *chloroform in preference to the less dangerous anesthetic*, ether?

6 —What is the best way of administering chloroform?

To the first question the answer is yes, for the majority of cases, provided it is given by one who is skilled in its use and not only knows how to give it but to detect signs of danger It is not as safe as ether at any time, other things being equal, and never safe in the hands of a tyro

To the second question the answer is, watch the respiration, *because as soon as enough chloroform is used to endanger the circulation the respiration will show some signs of abnormality either in depth, shallowness or irregularity* In other words, the very effect of the drug may be to cause such deep and rapid respirations that an excessive quantity of the drug is taken into the lungs and continues to be absorbed even after the inhaler is withdrawn

As there is always a fall in pressure under chloroform it is difficult to feel the radial or temporal pulse and the respiratory center recognizes the degree of arterial depression, which its sister vasomotor center has permitted by finding that its blood supply is insufficient *As respiration fails first it should be watched first* Finally, it is only by watching the respiration that we can tell how much chloroform the patient is getting We do not watch this function for danger alone but to tell us of the dose

The answer to question three is that death is always due in healthy animals to respiratory failure accompanied by circulatory depression, which latter may be severe enough to cause death even if artificial respiration is used skillfully Death only occurs in the healthy animal when chloroform is given in excessive quantities

Question four is impossible to answer for man from the basis of experimentation, as we can not produce identical diseased states in animals with those developed under various conditions in man The physician having a case of heart disease should always advise the patient of the danger of any anesthetic and he should remember, whether it is wise to tell the patient or not, that anesthesia always means a step toward death even in the healthiest of men In the event of a death under chloroform the physician is not to blame if he has taken proper preliminary precautions and given the chloroform properly

Every one is agreed that the patient taking chloroform should have plenty of fresh air and in India we understand that to all intents and purposes patients are operated on in the open air, at least as compared to the closed rooms necessary in America and Europe This free supply of air is important, whether we believe death to be imminent from cardiac or respiratory failure, but this supply of air matters little to the patient if he does not breathe freely nor does the dose of chloroform amount to aught if it is not drawn into the chest The dose of chloroform is not the amount in the inhaler but the amount taken into the chest and finally the amount absorbed by the blood vessels The rapidity and depth of respiratory movements is therefore, as Lawrie asserts, the entire key to the situation We watch a windmill over a well to see if it is pumping into a reservoir a given quantity of water If the windmill works irregularly so that we know its pumping action is deranged we separate it from the pump until the wind blows steadily, in order that it may pump regularly Similarly we withdraw chloroform, as Lawrie says, whenever respiration becomes disturbed in rhythm or when struggling disturbs it, because it is the first indication that the drug's action is uncertain and because there is no telling the dose which is absorbed While watching the respiration will not warn us of a sudden cardiac arrest in fatty heart plus chloroform depression, neither will the pulse give us such warning and we are confident that the statement of the Hyderabad Commission that the *respiration should be watched is correct*, for we believe from a long series of observations that gradual cardiac failure never occurs without producing respiratory changes from the very first In other words, we do not believe that in a healthy heart chloroform can cause serious disorder without as a result of beginning disorder disturbing respiration and, second, that in a healthy heart a quantity of chloroform sufficient to disorder it will by its direct action disorder the respiration If, as an extra precaution, one assistant watches the pulse while the other watches the respiration, very well, for though the respiration is the more important function the man watching the pulse might discover an irregularity which the anesthetizer may not see reproduced in the respiratory action, but as divided attention generally means a slighting of both objects in view Lawrie is right in insisting on the pulse being let alone

In answer to question five we have several points to offer 1 Hot climates where ether is inapplicable and where a free circulation of air increases the safety of the patient, 2 Chloroform may be used whenever a large number of persons are to be rapidly anesthetized so that the surgeon may pass on to others and save a majority of lives, even if the drug endangers a few, as on the battlefield where only a small bulk of anesthetics can be carried 3 Its employment is indicated in cases of Bright's disease requiring the surgeon's attention, owing to the fact that anesthesia may be obtained with so little chloroform that the kidneys are not irritated, whereas, ether, because of the large quantity necessarily used, would irritate these organs Quantity for quantity, ether is, of course, the less irritating of the two, 4 In cases of aneurism, or great atheroma of the blood vessels, where the shock of an operation without anesthesia would be a greater danger than the use of the anesthetic, chloroform is to be employed, since the greater struggles caused by ether and the stimulating effect which it has on the circulation and blood pressure might cause vascular rupture, 5 In children or adults who already have bronchitis, or who are known to bear ether badly or, in other words, have an idiosyncrasy to that drug, chloroform may be employed, 6 Persons who struggle violently and who are robust and strong are in greater danger from the use of chloroform than the sickly and weak, probably because the struggles strain the heart and tend to dilate its walls

The safest method of administration is by Lawrie's or Esmarch's inhaler because these provide free circulation of air and do not distract the attention of the anesthetizer from the respiratory movement by complicated apparatus Apparatus much like these in allowing a free amount of air, are the Hyderabad chloroform inhaler, or open-ended cone with Krohne and Seseman's respiration indicator attachment The Junker inhaler, even with its modifications, is too complicated and cumbersome and while less chloroform is wasted in administering the drug it must all be thrown out of the bottle afterwards If used at all it should be used with the increased air supply and respiration indicator of Krohne and Seseman

We agree so heartily with Lawrie's conclusions that we print them below

1 —The chloroform should be given on absorbent cotton stitched in an open cone or cap (A depression made through the opening in the inside flannel bag will answer as well)

2 —To insure regular breathing, the patient lying down with everything loose about the neck, heart and abdomen, should be made to blow into the cone, held at a little distance from the face The right distance throughout the inhalation is the nearest which does not cause struggling or choking or holding of the breath Provided no choking or holding of the breath occurs, the cap should gradually be brought nearer to, and eventually may be held close over, the mouth and nose as insensibility deepens

3 —The administrator's sole object while producing anesthesia is to keep the breathing regular As long as the breathing is regular and the patient is not compelled to gasp in chloroform at an abnormal rate there is absolutely no danger whatever in pushing the anesthetic till full anesthesia is produced

4 —Irregularity of the breathing is generally caused by insufficient air, which makes the patient struggle or choke or hold his breath There is little or no tendency to either of those untoward events if sufficient air is given with the chloroform If they do occur the cap must be removed, and the patient must be allowed to take a breath of fresh air before the administration is proceeded with

5 —Full anesthesia is estimated by insensitiveness of the cornea It is also indicated by stertorous breathing, or by complete relaxation of the muscles Directly the cornea becomes insensitive, or the breathing becomes stertorous, the inhalation should be stopped The breathing may become stertorous, while the cornea is still insensitive The rule to stop the inhalation should, notwithstanding, be rigidly enforced and it will be found that the cornea always becomes insensitive within a few seconds afterwards It is only necessary to add that the patient should be so dressed for an operation that his respiratory movements can be easily seen by the chloroformist In the climate of India this is not difficult to manage, but it is rather more so in the climate of Europe, so that in this respect, and in this respect alone, the chloroformist in England and America is placed at a distinct disadvantage compared with the chloroformist in India

Note —Since writing this report two important papers upon this subject have appeared in the London *Lancet* The one by Gaskell and Shore, in which they carried out a line of ingenious cross-circulation experiments, and from which they conclude that the fall in blood pressure seen under chloroform is due to cardiac rather than vasomotor depression, and another paper published by Lawrie, in the London *Lancet* for Feb 11, 1893, in which he refutes the statements made by Gaskell and Shore, and details experiments which he believes combat those of the two investigators just named

The concluding paragraph of Lawrie's latest contribution to the subject states the facts so clearly and is so in accord with what we have tried to set forth in our own report that we can not do better than quote the paragraph

"The Hyderabad Commission's work proves that, while Syme's principles are right, there is no such thing as a safe method of chloroform administration It is no longer a question of the superiority of the London method or of the Edinburgh method, absolute safety can be attained neither by watching the respiration nor the pulse for signs of danger—which are in either case proof of improper administration or of overdosing Moreover, overdosing may take place whether the anesthetic is given on lint or on a towel, or on a cap such as we use, or with Junker's or Skinner's or any other form of apparatus The all-important point is that the breathing shall never be interfered with in any way Safety under chloroform can unquestionably be insured, but it can only be so by attending to regular natural breathing, and, whatever method is employed, no one can deny that it is the bounden duty of the chloroformist to maintain natural breathing throughout the whole period of administration To maintain natural breathing requires careful training and considerable experience, but if those conditions be fulfilled it is impossible to produce anything with chloroform but anesthesia, and the Hyderabad Commission has shown that anesthesia alone is entirely free from risk," provided the drug is not pushed too far and that the patient is in ordinary health We would prefer to make the last sentence read "Anesthesia can be safely produced by chloroform"

SELECTIONS

Summary of the Surgery of the Tendons[1]—With Six Illustrations from Lejars—By John B Hamilton, M D, LL D, Chicago

The Surgery of the Tendons is the somewhat ambitious title laid down on the program as the title of my paper, but as time has not permitted me to review the whole subject in extenso, I will ask you to excuse my shortcomings, while I give you a condensed statement that will probably need no further condensation at the hands of your secretary After all, I think most of the ideas that are new, or even presented in new form, can be stated in very few words

I will pass over lightly the literature of the tendons, although that is very extensive, not only in medical literature, but in general literature From the time Achilles' mother, Thetis, dipped him in the Styx, to make him immortal, by grasping tightly the tendons that have since borne his name, down to the middle ages when ham-stringing an enemy was a pleasant pastime of the bold Barons, the tendons have had considerable prominence

In the surgery of modern war, where the wounds are made by bullets and rarely by bayonet or saber, the tendons are rarely wounded, for the very obvious reason that bullet wounds in battle are received on the body in exact proportion to the exposed area

In civil life, the tendons are subject to dislocations more frequently than to wounds

These accidents, though attended by few pronounced symptoms, need careful attention

Contusions and punctured wounds need but scanty reference, owing to the lack of vascularity, contusion of a tendon is difficult to produce Punctured wounds, when produced by any instrument causing laceration of the tendon fibers, are usually accompanied by retraction of the cut fibers and local necrosis of the connective tissue filaments, when made by a cutting instrument held parallel with the fibers, the wound closes with great rapidity, first by swelling of adjacent fibers from limited congestion, and second, by direct adhesion The tendon sheath, however, made up as it is of loosely united connective tissue, is exceedingly liable to infection, and tenonitis, so called, almost invariably runs its course in the tendon sheath Notwithstanding the fact that longitudinal wounds or separations of the tendons heal with rapidity, yet the resulting cicatrix impairs the efficiency of the tendon for a longer or shorter period, according to the area involved Sometimes this impairment amounts to total suspension of the functions of the members, and the practical deduction from this lesson is, that *in opening abscesses lying underneath a tendon, the incision should invariably be made at the side of the tendon, not through it* This practical advice, I believe, is not generally adhered to in the cases of finger abscess, but it should be In abscesses of the fingers the original point of infection is usually the periosteum, the pus seeking exit in the line of least resistance usually projects from under the tendon on either side, and if the tension be not relieved at this time the adjacent bone participates in the inflammation, and it too becomes necrosed

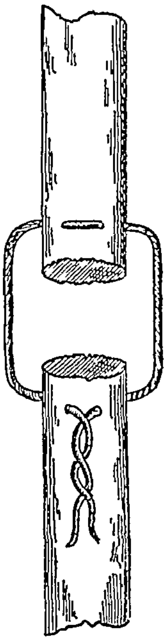

Fig 1 Tendon Suture of LeFort

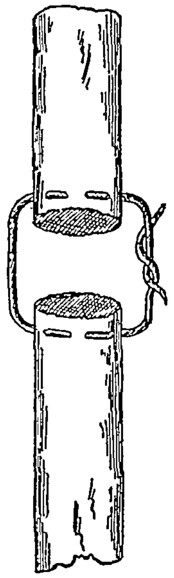

Fig 2 Tendon Suture Woflar After Lejars

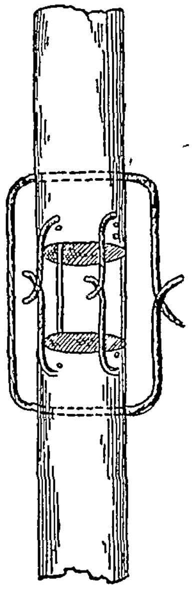

Gig 2 Suture of LeDentu

It has been mentioned that the cicatrix impaired the functions of the tendon Not only does this impairment occur but, owing to the feeble circulation of the tendon, the absorption of the redundant cicatricial tissue is slow, and sometimes the impairment is permanent The sheath and the adjacent connective tissue being richer in blood vessels, not only accomplish repair sooner, but they more speedily remove the cicatrix

Theories of repair of tendons after injuries have undergone the same successive changes as that of repair of wounds elsewhere The theory of Hunter, that the elements of the blood were alone concerned in the repair of tendons, held sway until Bouvier in 1857 asserted that the tendon sheath by proliferation filled up the interspace between the ruptured ends Henle, Robin, Adams, Paget, Brodhurst, adhered to the theory of repair by exudation and direct union of the ruptured ends Turcker, Donders, Virchow, Remak Kolliker, Cornil and Ranvier have confirmed in the main the cellular theory of Bouvier by examination of cicatrices of tendons in man and animals and experimental tenotomies

---

[1] Read at the Mitchell District Medical Society

According to Krauss, who wrote a memoir on this subject in 1888, "the first alteration in the tendinous ends is like a degeneration, a shriveling at the center and a granular appearance of their protoplasm But the principal modifications consist in a proliferation of the tendon cells, in which there is often observed the karyokinetic figures, and a corresponding enlargement of the fibrillar tissue Afterwards the cells become round or angular and are prolonged from the fibrils, and the prolongations are found in the peri- or intra muscular fascia "

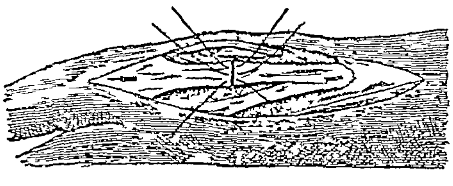

Fig 3 Suture by Anastomosis (Method of Schwartz) After Lejars

We may conclude that repair is complete when the functions of the muscle are restored, but as the restoration of the tendon necessarily depends upon the length of the separation space, we must interfere if we desire to secure early union

The question of suture of tendons is the one that most concerns the practitioner Shall the ruptured tendon be sutured or left to nature?

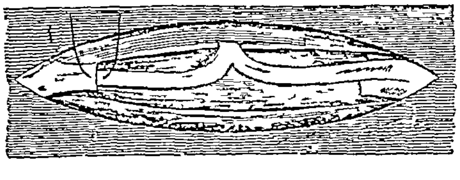

Fig 4 Method of Czerny After Lejars

Galen opposed the suturing of tendons, and so long as his authority remained undisputed, the interdict prevented it The credit of the change is given to Avicenna, and since his day surgeons have vied with each other in producing new forms of sutures, both in material and manner of application My distinguished colleague, Professor Nicholas Senn, has been engaged for some time past in an exhaustive research of the medical literature of intestinal sutures, and the fruits of that research will soon appear in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION From that learned and instructive paper it will appear that it is almost impossible at this day to devise a new form of suture This, however, only further corroborates the keen suggestion of Aristotle, "that probably all art and all wisdom had once been fully explored and again forgotten "

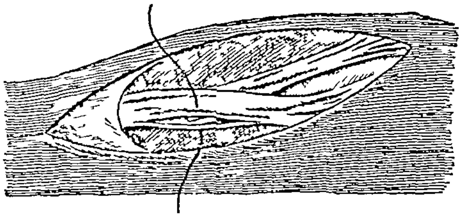

Fig 5 Suture by Anastomosis (Method of Tillaux and Duplay) After Lejars

Not to take up your time with further historical allusions, I will only mention the sutures of LeFort, Wolfler, LeDentu, Tillaux, Duplay, Schwartz and Czerny

The material most in favor at present is horsehair, and chromicized catgut Subcutaneous wounds of the tendons do not require suture unless the distance between the ends be very great, but all open wounds severing tendons require that the tendon be sutured The difficulty which has led to so many forms of suture is the separation of the fibers by reason of their retraction, a complete ligature of the tendon could only result in strangulation necrosis of the ends The drawings herewith from Lejars give you a fair idea of the different methods Of these, perhaps the most ingenious is that of Tillaux and Duplay, which consists in suture of the peripheral end of a cut tendon in a slot cut in an adjacent tendon Finally, we have the proceeding of Czerny, by which a splicing is effected by transplantation Transplantation of tendon sections has been made by Gluck, Georges Assaki and Fargin Chassaignac as long ago as 1853 had united a tendon to the skin, in a case of section of the flexors of the thumb and index finger, and by the tension on the cutaneous cicatrix to which the tendon was united had good motion of the thumb and finger

Where the separation is of long duration, both proximal and distal ends must be freshened

LUXATIONS —Dislocations of the tendons are quite common, the most common being the dislocation of the long head of the biceps, from the bicipital groove of the humerus This accident is so thoroughly described in most works on dislocations, I will not dwell upon it here The dislocation of the peroneal tendons from their groove at the external malleolus has escaped very much notice in the systematic works on surgery I have seen two examples of this dislocation within the past year Both were employes of the C, B & Q R R, and both were switchmen The accident may be recognized by pain, inability to turn the foot outwardly without pain, and the tendon may be seen and felt resting on the external surface of the malleolus One of my patients acquired the habit of throwing the tendon out of its groove at will, the operation itself being painless The attempt to walk while the tendon was in this abnormal position was very painful He could reduce the dislocation easily by manipulation The action seems to be produced while the weight of the body is thrown on the ball of the foot, the foot being extended and slightly rolled toward the inner border Once produced its recurrence is common The accident is also alleged to have occurred to horseback riders

The reduction of dislocation of the peroneal tendon is easily effected, but the difficulty is to retain it in position Fixation by the Martin's bandage, incision and suture have each their advocates, and Madyl of Vienna deepened the malleolar groove with a chisel, in my own cases the men being on the hospital list of the railroad company, declined to submit to an operation There is a strong probability that suturing the peroneal tendon to that of the flexor longus policis, which is adjacent, might prevent its return, but the operation of Prof Albert seems to fully meet the indications —*St Louis Medical Mirror*, *Sept*, *1893*

Trional —Koppers (*Intern Klin Rund*, 29, 30, 1893), observed the action of trional in twelve patients and arrived at the following conclusions In most cases of simple insomnia 15 grains sufficed to induce sleep within half an hour, 20 or 30 grains may be given if necessary, but with still larger doses the effect does not seem to increase proportionately Where pain is present some, though not much, sleep results Owing to the rapidity of its action trional is best taken at bedtime in some warm vehicle, such as milk or tea The after effects consisted only in slight heaviness in the morning, owing, apparently, to the direct action of the drug upon the cortex of the brain, and some slowing of the heart's action If necessary, it also can be administered per rectum, the action thereby not being lessened —*British Medical Journal*, Sept 9, 1893

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

SUBSCRIPTION PRICE, INCLUDING POSTAGE
PER ANNUM, IN ADVANCE $5 00
SINGLE COPIES 10 CENTS

Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
NO 68 WABASH AVE, CHICAGO, ILLINOIS

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J DUNGLISON, M D , Lock Box 1274, Philadelphia Pa

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION

This is obtainable at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association All that is necessary is for the applicant to write to the Treasurer of the Association, Dr Richard J Dunglison Lock Box 1274, Philadelphia Pa , sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society with five dollars for annual dues and subscription for THE JOURNAL Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly

SATURDAY, OCTOBER 14, 1893

EXTRA-UTERINE PREGNANCY

Nothing in surgery is more typical of the advances which modern science has made than is the treatment of extra-uterine pregnancy Although the axiom that death was due to hemorrhage and that the bleeding vessel must be secured was laid down over a century ago, it was a half century before the precept became practice and not until the present time, following the teaching of MR TAIT, has the practice received the sanction of the operators of the world If there was nothing else of which he might be proud, the abdominal surgeon might well point to the life saving record in ectopic gestation

Although the modern literature of the subject has assumed enormous proportions, beginning with the classical work of DR PARRY in 1876, there are still many points on which there is by no means a consensus of opinion in the profession In the first place, there is a division as to the possibility of an absolute diagnosis previous to rupture The disease is simulated by so many conditions, that it is unwise to lay down a train of symptoms which shall be taken as convincing evidence of the existence of an ectopic pregnancy So closely does miliary disease of the ovary simulate ectopic pregnancy that skilled observers, men of wide experience, have been misled The so called "classical symptoms" of extra-uterine pregnancy are all here—the absence of one or more monthly periods, followed by a hemorrhage from the uterus, the morning sickness, the boggy tumor in the ovarian region—all may be present in tuberculosis of the ovary and may easily deceive the physician into thinking the case one of misplaced pregnancy Again, the seeming extra-uterine pregnancy proves at the operating table to be a Fallopian tube filled with pus and causing the pain and hemorrhage that have given rise to the mistaken diagnosis A pedunculated fibroma lying to one side of the uterus may present close resemblance to the graver trouble, or a normal pregnancy in a thin-walled uterus may produce such symptoms as to render a positive diagnosis between the two conditions possible only after weeks of anxious waiting

Men of the rare opportunities of study and the large experience of MR TAIT and DR JOSEPH PRICE confess that they have been misled repeatedly and are almost willing to say that a diagnosis prior to rupture is impossible

MR TAIT in his monograph on ectopic pregnancy and pelvic hematocele, says

> "I have never but once been called upon to make an examination until the rupture had occurred, and in that case there was neither history or symptoms which enabled us to do more than determine that there was tubal occlusion, not, indeed until the rupture occurred and the abdomen was opened was a diagnosis possible Under these circumstances I think I may be excused for maintaining a somewhat skeptical attitude concerning the correctness of the diagnoses of those gentlemen who speak so confidently of making certain diagnoses in cases of tubal pregnancy before the period of rupture, and who speak with equal confidence of curing the cases by a puncture, either simple, medicated or electrolytic"

DR PRICE is even more positive in his opinion as to the difficulty, if not impossibility, of diagnosis previous to rupture In a recent paper he says

> "*Exceptionally*, if *ever*, is the trouble recognized before rupture The few cases recorded have all been by men with one experience, with very little knowledge of the murderous troubles found in the pelvis A few surgeons, with an experience of nearly one hundred sections for ruptured tubal pregnancy, have never found one unruptured"[1]

In the face of all the evidence on the subject it would seem that the diagnosis that is reported as made before rupture, is rather the result of a happy chance than the outcome of knowledge and weighing of symptoms on the part of the attendant

After rupture the diagnosis becomes easy, though rupture has many times been mistaken for an abortion by the attendant physician The sudden collapse with all the signs present of internal hemorrhage and the agonizing pelvic pain present a picture to the mind so vivid as to make mistake impossible A pelvic examination and the finding there of a boggy mass to one side of the uterus would settle the case beyond a doubt and one feels inclined to ask if, in those cases that have been mistaken for abortion, a sufficiently thorough examination had been made or if the doctor merely took the woman's statement that she was aborting

Rupture takes place either into the peritoneal cavity or between the folds of the broad ligament If into the peritoneal cavity the wretched mother rapidly succumbs to the loss of blood and the peculiar and excessive shock that follows the accident Rarely, it happens that the rupture takes place into the broad ligament and the fetus, developing in its new position, goes on to term and dies, condemning its bearer to invalidism and all the horrors of abscesses breaking into bowel or bladder and discharging the bones of her unfortunate offspring

---

[1] Medical and Surgical Reporter, Sept 30 1893

It would seem as if common sense would point out the treatment In any such hemorrhage from another part of the body, the physician would scarcely do his duty did he not seek out the bleeding vessel and secure it, yet we find men advocating *anything rather than the surgical treatment* Puncture of the sac, injections into it of lethal substances, and electricity have all had their supporters These agents find their use only previous to rupture and the uncertainty of diagnosis, and the fact that even in the hands of experts they have failed to save the patient from an operation are a sufficient answer to their claims

That cases have recovered without operation is no reason that the surgeon should shirk his duty The moment rupture occurs, the abdomen should be opened and the hemorrhage stopped by the removal of its cause In no event should the case be allowed to go on in the hope that the patient, by some providential agency, may survive The dangers of the hemorrhage, with the peritonitis and septicemia that follow the accident are too great to be set aside

An important point in the surgical treatment is whether, in a ruptured tubal pregnancy of one side, the other side should also be removed to prevent the recurrence of the accident In a paper on "Repeated Extra-uterine Pregnancy," published in the JOURNAL for Sept 16, 1893, DR MCKELWAY reports a case where the patient, after providentially escaping an untreated tubal pregnancy of one side was seized nine months later by a similar accident on the remaining side, from which she escaped only after a prompt operation and heroic measures In discussing the case the author says "My study of this and other cases leads me to the conclusion that both tubes and ovaries should be invariably removed in every case of ectopic gestation " In view of the fact that the causes of a pregnancy in one tube may be present in the other, is it right that the woman should be exposed to the chances of a repetition of the accident The question is one of great importance It is possible that the accident may never recur and there are many instances where the patient has subsequently had normal pregnancies and remained healthy To offset this are the cases where the second ectopic pregnancy has followed a normal pregnancy In the discussion which followed the paper, the conservative ground was taken that the other side should not be removed unless there was evidence of existing disease Removal of the sound side adds slightly to the risks of the operation by increasing the shock and prolonging the operation, but, in a patient already at death's door and where safety depends on a short, dextrous operation, these considerations weigh heavily The question is one to which our operators with large experience should turn their attention, and it is for them to decide whether the chances of a presumably healthy tube being the site of a subsequent pregnancy are sufficiently great to call for the more severe procedure

Another point is raised as to the treatment of the placenta in case the pregnancy is so far advanced as to render the removal of the entire sac impracticable or dangerous Various plans of procedure have been devised The sac has been stitched to the abdominal wound and drained it has been sealed and left in situ to be absorbed—all with more or less good results Sound surgical sense would teach that the safety of the patient lies in the complete removal of the sac wherever possible, and, with the agents at our command, heat and gauze packing, the hemorrhage can be controlled and the placenta removed in almost every instance with a prospect of safe recovery for the patient Where it has grown so intimately to surrounding structures—often intestines and important viscera—it should be thoroughly cleansed by repeated washings with boiled pure water and hermetically sealed, in order that it may be digested and gradually absorbed with the least possible chance of septic decomposition

A third question is whether, in case the patient survive a primary rupture the case shall be allowed to go on to viability of the child in order to save the life of the child It is an obstetric maxim about which there is not the slightest cavil, that the mother's life is to be respected more than the child's, and it would seem that the added risk to the mother should weigh against the child's life and therefore the misplaced product of conception should be removed as early as it is discovered Delays in this as in other matters are full of danger

From the beginning to the end, extra-uterine pregnancy is full of danger The sudden urgency of the accident, coming as it does without warning, makes it a matter of the greatest concern to the specialist and the general practitioner alike In the majority of instances, the diagnosis must be made by the family physician, and the specialist comes in only to confirm the general practitioner's opinion and to perform the life saving operation

"Tubal pregnancy is a grave, perilous trouble from the very instant of its inception, and from the instant of its first recognition there should be no suspension of the vigil over it There is but one safe choice, and that is prompt removal when the accident is first recognized " Such are the words of a successful operator and they contain a truth that it were well to understand, and knowing to heed

Blank applications for membership in the ASSOCIATION, at the JOURNAL office

THE INTERNATIONAL PUBLIC HEALTH CONGRESS

The meeting of the Public Health Congress this week constitutes one of the most interesting of the series of World's Fair International Medical Congresses Interesting alike to the physician and the laity, the proceedings of the Health Congress are of value to all mankind The cure of disease largely concerns the readers of the JOURNAL, but the prevention of disease appeals alike to all

We are sure, therefore, that the address of PRESIDENT DURGIN which is printed exclusively in the JOURNAL, will be widely appreciated, not only on account of its intrinsic interest, but because the author as Chairman of the Board of Health of the city of Boston, for the past twenty years, has had exceptional advantages for the study and solution of most of the complicated questions of municipal sanitation, that are likely to interest health officers throughout the world

The merging of the American Public Health Association with the International Congress of Public Health proved a wise measure, as the considerable number of papers on the program by foreign authors added much to the interest and success of the meeting

That veteran of sanitary science, DR JOHN H RAUCH, was Chairman of the Committee of Arrangements, and he was ably seconded by DR M R BREWER, the Secretary of the Committee

THE AMERICAN PUBLIC HEALTH ASSOCIATION

This organization has been in session during the past week in connection with the International Sanitary Congress, as will be seen elsewhere in the columns of the JOURNAL It has arrived at its majority This is its twenty-first annual meeting The necessity for such an Association was felt immediately after the war by those who had been trained in the military service and had subsequently been called to act as health officials in a civil capacity The war demonstrated the importance of preventive medicine A fighting force has to be kept in fighting condition

Textbooks on sanitary science were few, and the best of them were not adapted to the civic health officer Each such health officer practically was acting independently The necessity for bringing together, in one body, those interested in sanitary matters, for the purpose of inaugurating measures for the restriction and prevention of contagious diseases and for the diffusion of sanitary knowledge among the people, was so apparent that after several years of conference and correspondence the Association was formed in the fall of 1872

The only attempt at organization prior to this was the quarantine convention, composed of representatives from the cities of Baltimore, Philadelphia, New York and Boston DR WILSON H JEWELL of Philadelphia, was the leading spirit in this movement This was at the time when quarantine was the only preventive measure used to combat foreign pestilence This convention, after an existence of four or five years, had been extinct some time before the creation of the American Public Health Association For several years the new Association required a great deal of labor and self sacrifice on the part of those who had inaugurated it to keep it in existence The growth of the Association and the work it has accomplished prove the correctness of the views of its founders Its membership has been augmented from year to year, until it now constitutes the largest and strongest sanitary body in the world, and embraces in territorial extent the United States, the Dominion of Canada and the republic of Mexico Under the impetus given by its work, State and local boards of health and sanitary associations have been organized, sanitary publications increased, and hygienic knowledge widely diffused

The terms of its membership are sufficiently broad to include all who are interested in public health questions Its transactions not only contain reports of patient laboratory investigation, but the practical conclusions of those actively engaged in sanitary work

Preventive medicine is necessarily and entirely disinterested and of the highest type of benevolence, and the American Public Health Association should have the cordial support of all who are interested in the well being of humanity

THE INSPECTION OF MERCHANTABLE WATERS

The vast number of places in our country where mineral and table waters are sold has made it a matter of solicitude whether or not they are what their label represents It is not only distressing to be doubtful about the quality of the bottled waters, but it amounts almost to panic when we reflect that what purports to be Brother HART'S APOLLINARIS may be a vile mixture, filtered from the Chicago River, or pumped from the nearest hydrant, and that even Wisconsin, Waukesha or Chippewa Spring water, to say nothing of the unnamed thousands, may also be either extremely stale, or altogether fraudulent in any market

There is no question but advances in civilization will ultimately require protection of the people against fraud, but as yet we know of no municipal ordinance which requires the inspection of bottled waters Not only is it an act of fraud to sell waters under a false label, but it is in effect criminal, when persons imagine they are receiving medicinal waters as prescribed by their physician

There is a certain water in West Virginia of great value in gastritis Now if any physician in any city knowing its virtues, should prescribe it, and the patient obtain the product of the hydrant instead, no words could sufficiently characterize the fraud, and yet we are credibly informed that there exists in the city of Chicago, a factory where not only the labels, but the corks and bottles, may be procured in exact imitation of any known water We doubt extremely whether Chicago is alone in this iniquity, and it is more than probable that a large percentage of the water sold in bottles is fraudulent

The mere suspicion of fraud in the sale of these waters, is enough to cause many to turn to other beverages

"If she be not fair to me,
What care I how fair she be"

If this be true of the bottled waters, what can we say of the waters delivered to customers by incorporated companies in bulk? The water *may* be good, but nobody can say so except the vendors themselves, for there is no qualified inspector

The need for water inspection is therefore one of urgency, and we shall be pleased to record the date of passage of the first municipal ordinance for the prevention of fraud in the sale of potable and mineral waters

THE MISSISSIPPI VALLEY MEDICAL ASSOCIATION

The annual meeting of the Mississippi Valley Medical Association was held at Indianapolis on October 4, 5 and 6, under the presidency of Dr R S Sutton of Pittsburgh

The attendance was less than at some meetings previously held, but it is easily accounted for by the recent financial stringency and the Pan-American Medical Congress The proximity of the World's Fair at Chicago, and to a less extent the St Louis Exposition served to attract members in those directions

As usual, the American Medical Association members constituted about four-fifths of those attending, and their share in the scientific work was proportionate

The papers were excellent, and we print in other pages an abstract of them

The discussions were well sustained, animated and interesting They would have been more voluminous but for lack of time,—the great number on the program allowed but limited time for discussion

The high standard of the papers read at this meeting is a source of gratification to the well wishers of the Association

A MEDICAL EDITOR'S RESIGNATION

Dr Cyrus Edson has resigned from the editor's chair of the *Doctor of Hygiene*, of New York At least he is reported as saying that his name will not appear again as responsible for its management The journal was formerly known as the *Doctor*, but soon after its change of name and the entry of Dr Edson, then the Sanitary Superintendent and later a Commissioner of the Health Department, the make up of the paper became such as to attract attention The names and portraits of the president and officers were published on the front cover, as if it were an official organ of the Board and it purported to be "in the interests of American boards of health" Various schemes of a sanitary nature sought the columns of that paper, with the intention apparently of taking shelter under the roof of this bright project A water-filter company at the head of which Dr Edson's name figured, was among these The imputation, however, that the position of the latter as a health official was liable to misuse for private gain, led him to withdraw from the company There have been a great many resignations of late years in relation to the New York Board, but very little repose The politicians have their grip on it, and use it to the utmost of their power

ORGANIZATION A PROFESSIONAL NECESSITY

The *Medical News* of Philadelphia, which has been making many pointed appeals for a greater and stronger union, in a recent and able editorial on the attitude of the lay press to the medical profession says

> "A Philadelphia newspaper lately made itself the agent of some patent medicine cure-all, and distributed thousands of bottles over its counter
>
> "There remains, of course, the humiliating confession that the existence of the newspaper doctor and of the newspaper debauch in quackery is indirectly and in large part the fault of the profession itself, dependent upon the fact that we are a non organized profession, and that what organization we have is not used in the practical righting of medical abuses Thus, again and perpetually, recurs the truth that every medical scandal and every aspect of our powerlessness resolves itself into our sins of disorganization, and of non interest in practical matters and in preventive medicine Out of a hundred thousand physicians in America hardly a hundredth part are active members of the American Medical Association, and the section meetings of "congresses" of physicians could almost always be held in an ordinary private sitting room of a workman's cottage—so slim is the attendance And when we do meet we discuss the symptoms and treatment of individual cases of illness, leaving out of consideration the production of disease, the prevention of it, and the domination of legislation, the newspapers, and the lay world by the quack and the pill-vendor
>
> "How can we bring any influence to bear upon the newspapers if we present the spectacle of a disunited and factional lot of scramblers and indifferentists? There are many of these newspapers who are simply ignorant and thoughtless as regards the disgrace of their advertising columns, and who could easily be shamed out of it if we were but united among ourselves, and would use our united strength for matters of practical reforms of medical abuse and preventive medicine Organize, and use organization for the world's sake! is the command of professional honor and of benevolence"

Honors to Prof Pozzi—The Chicago Gynecological Society, of which Dr E J Doering is President, gave a dinner to Prof S Pozzi, Professeur Aggregé to the Faculty of Medicine and Surgeon to the Lourcine-Pascal Hospital of Paris, on Friday, October 6

SOCIETY NEWS

Mississippi Valley Medical Association

Abstract of the Proceedings of the Nineteenth Annual Meeting held at Indianapolis, Ind , Oct 4, 5 and 6, 1893

FIRST DAY—GENERAL SESSION

The Association met in Plymouth Church, and was called to order by the Chairman of the Committee of Arrangements, Dr George J Cook of Indianapolis

Divine blessing was invoked by the Rev Frederick E Dewhurst

Governor Matthews was introduced and delivered an

ADDRESS OF WELCOME

The President, Dr R Stansbury Sutton of Pittsburg, was introduced and delivered the President's Address He selected for his subject,

FIBROID TUMORS OF THE UTERUS

After giving a definition of these tumors the author dwelt upon the etiology, which he said is still a mystery They are more frequent in the black than in the white race In both races they are more frequent in the body than in the neck of the uterus, and more frequently situated in the posterior than in the anterior wall After the menopause is established these tumors generally disappear, unless they have undergone cystic degeneration Bearing on this point Dr Sutton reported an anomalous case The patient was 43 years of age, she had never menstruated in her life, had never shown any physiological evidence of ovulation, had been twice married, was then a widow and childless She had for ten years a large fibro-myoma of the uterus, which thus far gave no evidence of atrophy

With regard to the pathology, the tumor always has its origin in the substance of the uterine wall or sub peritoneal connective tissue

The symptoms accompanying the presence of these tumors in various localities and stages of growth are widely different However, the class of indications are patent as found in the vast majority of cases, and may be tabulated as follows 1, vague pain in the pelvic region , 2, pain referred to the front or back of the leg , 3, irritability of the bladder or rectum , 4, uterine tenesmus , 5, menorrhagia or metrorrhagia , 6, dysmenorrhea , 7, profuse leucorrhea , 8, serous discharge from the uterus

The diagnosis of very small fibro-myomata, when many of the leading symptoms are absent, is considered extremely difficult As far as the medical treatment is concerned, but little can be done for the relief of patients suffering from fibro myomata, and nothing for those suffering from those tumors which have undergone cystic degeneration Surgically, there are but two routes by which solid, uterine tumors can be removed, either through the vagina or by abdominal section With the exception of small tumors with a well defined pedicle, all sub peritoneal fibro-myomata are reached only by section of the abdominal wall Dr Sutton in one case divided the posterior wall of the vagina and through this opening delivered the tumor

SECTION ON GENERAL MEDICINE

Dr O Everts of College Hill, Ohio, Chairman

FORENSIC MEDICINE

This paper was read by Dr C G Comegys of *Cincinnati* The author had come to the conclusion, from his experience, that there are but few lawyers sufficiently informed in medical science to conduct a case in the interests of truth and justice, especially the most important cases in medical jurisprudence Every physician, as an expert witness, must have observed the embarrassment of lawyers in trying medical cases They ask questions enough, but from their lack of medical experience they are incapable of thoroughly understanding the answers of a witness, so that the proper interpretation of them, bearing upon the history of a case at the bar, may be reached, and when endeavoring to give the court and jury clear views of the subject by additional questions, they often confuse the whole investigation This disagreeable state of affairs is usually brought about by certain lawyers who have armed themselves by a superficial study of medical works for the occasion Dr Comegys believes that the high order of legal men will welcome well-trained men in medicine as coadjutors in the lofty work of establishing justice

PROBLEMS OF PUBLIC INTEREST CONCERNING THE INSANE, by Dr Orpheus Everts of College Hill, Ohio The author said there are several problems of public interest involved in the present relations of society to the insane Among the more important of these are questions of dependency and curability of the insane and the preventability of insanity The author summarized his conclusions as follows

1 —Intelligent provision for the insane implies provision for various classes, according to the capabilities of enjoyment and the exercise of variously impaired faculties

2 —Public provision for whatever class of insane persons implies housing, clothing, food, sanitary and moral discipline, amusement and employment for such as are capable of being amused and employed, and medical treatment for the sick The essential features of such provision are adaptability to the needs of each distinctive class

3 —Great, expensive, architecturally imposing palaces, providing alike for all classes, however serviceable they may have been, esthetically considered, in times past, as they unquestionably were, are no longer necessary nor appropriate to the needs indicated So long as the insane are comfortably housed, each class according to its condition, it is comparatively unimportant whether it be in large or small houses, cottages or palaces, connected or detached, in high or low buildings

4 —It is important that the insane of all classes be well fed under careful supervision , but whether in small or large dining rooms, by groups or congregations, is of little consequence , that it should be a matter of convenience rather than of number

5 —It is important that public institutions for the insane be well organized and administered

6 —It is wise to retain in office capable men who have demonstrated their fitness by successful management of affairs, so long as their capabilities continue to be elastic

CHOREA IN ITS RELATION TO RHEUMATISM

This paper was contributed by Dr I N Love of St Louis The author said that recently the pathology of this disease has been cleared up to a very considerable degree, so that now it is a definite affection and one especially incident to childhood Dr Love reported a case of chorea occurring in his practice with a marked history of rheumatism, it being one of ten cases observed and illustrative of this class The cases did not occur successively Between them other cases presented themselves *minus* the rheumatic history, but four of the number occurred in rapid succession with as pronounced rheumatic history Of the entire ten, seven were girls Among the exciting causes of the disease are irritation in the nostrils and adenoid growths in the vault of the pharynx Inasmuch as Kirkes, Tuckwell, Hughlings Jackson and Bastian support the embolic theory of the disease, and in consideration of the fact that chorea is so frequently associated with endocarditis, we should be on the alert to interrogate the heart when called to a case of chorea As matters now stand we have numerous exciting causes resulting in chorea

CHOREA , ITS PATHOLOGY AND TREATMENT

This paper was contributed by Dr H M Lash of Indianapolis So much uncertainty has existed regarding the pathology of chorea, that its treatment has been varied and widely different in its character and aim, amounting even to empiricism Under all forms recovery has been recorded , but it is certainly interesting to note the variety of views which have been from time to time, and which are still held, in regard to this most peculiar disease The author then gave the causes of chorea as laid down in the recent work on nervous diseases by Dr Landon Carter Gray He referred to the repeated experiments of Dr H C Wood, who announced his conviction that the choreic movements had their origin in the spinal cord and were directly due to paralysis or depression of the inhibitory function of the cells of the spinal cord Acting on the strength of this conviction, Dr Wood sought for a remedy that would strengthen the proper function of these cells, and he found it in quinin

Dr Lash then reported a case of acute chorea in a boy 13 years of age The choreic movements were constant, general and pronounced It was agreed to try Dr Wood's suggestion, and so the patient was put on full doses of quinin Twenty grains a day, in four doses, were given him for three days, when he showed considerable improvement The quinin was increased to 25 grains a day and given in that amount for three days more when the patient again reported There were no remaining symptoms of the chorea, and the quinin was gradually withdrawn The patient has remained entirely free from the trouble ever since, and without any future treatment of any kind Another similar case was reported with a successful result

DIPHTHERIA, ITS SPECIFIC DIAGNOSIS

This was the title of a paper read by Dr J C Culbertson of Cincinnati The author said that this disease is of peculiar interest because of its singularity in being more treacherous and insidious in its manifestations than any other affection that is met with by the practitioner of medicine The uncertainty of diagnosis had caused some excellent practitioners to adopt the pernicious habit of diagnosticating and treating all cases of sore throat, whether simple or malignant, as if they were true diphtheria True, the treatment designed for diphtheria may cure a tonsilitis, but inestimable harm may have been done in causing an unnecessary alarm on the part of the patient's family, and the disagreeable inconvenience that accompanies isolation of the patient and quarantining of the family, to be followed by the mockery of disinfection of non-infected apartments and perhaps destruction of clothing and furniture On the other hand, a case of diphtheria, diagnosed as a simple tonsilitis, may be the cause of breaking up a school or producing an epidemic, with an indefinite amount of sickness and many deaths A case was cited in point

Dr Culbertson then referred to the importance of utilizing the science of bacteriology, and mentioned the plan adopted by the New York City Board of Health of having undertaken to provide laboratory facilities for all practitioners of medicine in that city free of charge

A TREATMENT GIVING A LOW DEATH RATE IN CASES OF DIPHTHERIA IN HOSPITAL AND PRIVATE PRACTICE

Dr William A Galloway of Xenia, Ohio, read this paper The subject was treated from the standpoint of recent hospital practice, 234 cases with a death rate of 14 per cent under favorable sanitary surroundings The paper embraced reports from private practice of physicians who had given the treatment faithful trial during the past three years, who unhesitatingly commended its value and all were able to show a death rate below 10 per cent The subject was divided into the *hygienic*, in which the most careful attention was paid to the isolation and surroundings of patients, the *constitutional* and *local topical* treatment, the latter being considered by the writer as secondary in importance Under constitutional treatment, immediately the nature of the disease was suspected, the writer gave 1 grain of calomel for each year of the patient's age up to 18, repeating the dose in four to six hours and met the action of the mercurial with copious hot water injections This treatment was persisted in until the full action of the calomel on the liver and kidneys was obtained, relieving these two important excretory organs of the paretic condition caused by the absorption of the toxalbumin product of the Klebs-Lœffler bacillus Improvement in the patient's appearance was immediate and the mercurials acted freely The quantity of foul smelling grass green dejecta resulting is astounding There is no fear from salivation, as under the most heroic use of mercurials no symptom of salivation has been observed by the writer or his friends Internally corrosive sublimate was given up to 1-80 of a grain, with full doses of tincture of chlorid of iron and alcohol hourly at night and during the day Local topical treatment consisted of peroxid of hydrogen, one-quarter solution, for cleansing the throat, which was commended, while as an escharotic 12 grains of salicylic acid to 1 drachm of alcohol were used twice a day by the physician only It proved of great value in the writer's hands This escharotic is very powerful and should be used carefully if needed

THE STUDY OF A FATAL CASE OF ESSENTIAL TACHYCARDIA

This paper was contributed by Dr John C Sexton of Rushville, Indiana, in which he detailed the symptoms and clinical features of a case of essential tachycardia that died after thirty-five days illness The attractive feature of the case was the response to manipulative efforts, electrical and other, by the Doctor, to produce stimulation of the pneumogastric nerve and thus to slow the heart The paper then reviewed the ordinary symptoms of heart hurry as presented in the literature of the subject and some further remarks concerning the causation, symptomatology and treatment

Papers were also read by Drs R E Haughton of Midland, Texas, A Ravogli of Cincinnati, and others

The address on general medicine was delivered by Dr James F Hibberd of Richmond, Ind His conclusions were

1—That there is a rapid progress being made in preventive medicine

2—That our present conception of the complicated organization of the human body is based on the theory that the Creator in the beginning endowed vitalized matter with a perpetual law of virtue of which man has been developed, step by step, from primitive protoplasm

3—That there is no longer dubiety in the proposition that the cell is the unit of vital activity, and that all living beings are a single cell or an organization of cells and cell products

4—That the influence of the mind on vital activities, normal and abnormal, is not recognized as it should be, and that there is a line of study that would, if properly pursued, dissolve the agnosticism that has in the past embarrassed a knowledge of the reciprocal relations of matter and mind

SECTION ON OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY

Dr Arthur W Johnstone of Cincinnati, Chairman

The first paper in this section was read by Dr Rufus B Hall of Cincinnati, entitled,

OVARIOTOMY IN THE AGED

The author confined his remarks to patients who were 70 or more years of age He said it was generally conceded as true that any operation upon the old did not promise as good results as the same operation would upon the young or patients in middle life Especially was this true in reference to all abdominal operations necessitating a hard strain upon the system from shock, or from traumatism to vital organs during the operation, as we not infrequently have in the removal of large ovarian tumors Dr Hall maintains that the death rate is not greater than that which usually follows the same delayed class of operations on women between 40 and 50 years of age He had had but three ovariotomies upon women above 70 years of age In each of the first two cases the friends of the patients hesitated to have the operation made on account of the advanced age of the patients In each of these the operation was deferred until the patient was in extremis

Dr Hall then detailed three interesting cases of ovariotomy performed on patients, aged respectively 70, 70 years and six months, and 72 years Judging from the low mortality of the reported cases and from the work of the best known operators, the author is constrained to believe that ovariotomy in old women, if the kidneys are healthy, is as safe as in middle life

THE VALUE OF A CLOSE OBSERVATION OF OTHER MEN'S WORK

This paper was read by Dr William H Link of Petersburg, Ind He said it is by the tireless energy of originality and the endless application of original methods to both the expected and the unexpected in surgery, that has thus far pushed our work and its underlying science toward perfection By close and frequent observation, defects in technique and improper application of surgical measures may be noted and, having been recognized, may be avoided There is no field in which object lesson teaching is so effective, so fruitful of valuable practical results as in gynecological surgery The observer may not always know whether the operation he witnesses carries the patient on to recovery or the contrary, but, if a close observer, he is improving his own surgical judgment He is studying, rejecting, or adopting methods and aphorisms as they impress his intelligence or his reason approves By seeing work done under varying conditions and with different results we readily come to the conclusion that a private hospital is by no means necessary to successful work, that the pure air of a country or village home, or a clean room in a private residence in a city is as good a place for surgical work as the most painted and gilded hospital, and that no one need hesitate because his patient can not have the supposed advantages of some place specially set apart for the sick

Dr L H Dunning of Indianapolis, Ind, read a paper entitled

INTESTINAL OBSTRUCTION FOLLOWING ABDOMINAL SECTION

Of the complications following abdominal section, few are more fatal than occlusion of the intestines It may appear in a few hours after the section or not until several weeks have elapsed In this paper the author dealt with only acute intestinal obstruction The author is conscious of having met with but a single case in 130 abdominal sections, yet this case occurred two and a half weeks after what he had considered a very successful ovariotomy The question of the administration of cathartics in cases of suspected or threatened occlusion of the intestines is one oftentimes most difficult to decide Under such circumstances he is inclined to the belief that during the first week after section cathartics are indicated, and he prefers to administer 1 grain doses of calomel every hour for a few times, then administer 2 drachm doses of epsom salts every two hours until an action is obtained, or it is demonstrated that a harmful effect is being produced A distinct understanding of the pathological conditions possibly present must guide the operator in his search for the cause of the occlusion, and when found it should be dealt with in the shortest possible time consistent with the permanent cure of the patient

THE PRESENT STATUS OF THE TREATMENT OF UTERINE FIBROIDS

This paper was contributed by Dr Xavier O Werder of Pittsburg, and in the absence of the author, was ,read by Dr Thomas B Eastman of Indianapolis For the sake of convenience the author divided the treatment into the symptomatic and the radical, and confined himself to those views which seem to be generally accepted by the leading and unbiased authorities of the present day The principal symptoms produced by uterine fibroids requiring our attention are hemorrhage and pain Hemorrhage is one of the most constant and dangerous complications, and is due to diseased and hypertrophied condition of the uterine mucosa and hyperplasia of its blood vessels (Wyder), or according to the later researches of Semb, to a hypertrophy of the uterine muscles accompanying the growth of the myoma with a simultaneous hyperplasia of the blood vessels The operations practiced for the radical cure of myomatous growths are vaginal enucleation removal of the appendages, enucleation by laparotomy, and supra pubic hysterectomy The author then considered these operations at length

THE ERECT POSTURE FOR GYNECOLOGICAL EXAMINATIONS

This paper was contributed by Dr William B Dewees of Salina Kan , but was read by Dr John C Sexton of Rush ville, Ind

Digital examination per vaginam with the patient in the erect posture affords one of the most positive means for diagnosis in gynecology It is a well established fact that respiration, the various movements and attitudes of the body, as well as pathological conditions, change the conditions and environments of the viscera Thus the importance of posturing the patient in making physical examinations in gynecic practice becomes evident, as most of the symptoms of diseases of the intra-pelvic organs are more marked and very many only manifested when the patient is standing , while certain conditions of descent, prolapse or displacement, may entirely disappear or change when the pressure or the superincumbent weight of the abdominal viscera is removed by the patient being placed in the dorsal, semiprone, genupectoral, or high pelvic positions, therefore the erect posture is of paramount importance as an aid in diagnosis in this field of labor The author emphasized the advantage and necessity of digital examination in the erect posture, more particularly in examinations undertaken for a cure in women of 1, displacements of the uterus , 2, vesical and rectal disorders , 3, lack of perineal and vaginal support , 4, ovarian and tubal disorders , 5, abdominal and pelvic tumors , and 6, differentiation between abdominal tumors and pregnancy

Dr H O Pantzer of Indianapolis, read a paper entitled,

TUBERCULOSIS OF THE PERITONEUM WITH REPORT OF CASES

The author said that the prognosis and treatment of peritoneal tuberculosis have changed within the last decade The accidental discovery of its curability by laparotomy has shifted its clinical relations He then quoted the conclusions of Dr J Whitridge Williams, from the Johns Hopkins Hospital reports, 1892, on tuberculosis of the female generative organs He reported a case of primary genital tuberculosis, giving rise to a tubercular peritonitis, and tubercular disease of the abdominal parietes Case 2 was one of primary genital tuberculosis following childbed, sacculated ascites resembling an ovarian tumor Laparotomy was performed and the patient recovered Case 3 was one of genital tuberculosis complicated with a suppurative infection and pelvic peritonitis Laparotomy was done, followed by recovery of the patient This disease, from being regarded as a fatal and most intractable affection belonging to the domain of internal medicine, since its accession to the realm of surgery has come to be regarded as quite submissive A mistaken diagnosis had repeatedly led to the opening of the abdominal cavity Instead of an ovarian tumor an enlarged gall bladder, a hydronephrosis, or some other legitimate object of surgical interest being found, tubercular disease of the peritoneum in some of its multiple forms presented itself The abdomen was closed without any attempt at treatment, or at most the ascitic fluid was evacuated It was noted that these cases did better afterwards, and that some fully recovered In 1884 Kœnig advocated laparotomy as a curative measure for peritoneal tuberculosis, and the operation has been done by other surgeons since

TREATMENT OF DISEASES OF THE UTERINE APPENDAGES

Dr William H Humiston of Cleveland, Ohio, read a paper on this subject, in which he said the frequency and importance of diseases of the appendages are recognized by all practitioners of medicine The early recognition of the same is of unusual importance, as by instituting proper treatment at once we save a large percentage of them from a major operation and a prolonged convalescence Simple inflammatory conditions of the tubes and ovaries, before extensive adhesions take place can be successfully treated by rest, boro-glycerid, and iodin tampons, long continued hot water douches, thorough curettement of the uterus, followed by a course of galvanism He had cured a few cases where the ovaries were prolapsed and somewhat adhered, by adding massage to the above treatment But, as a rule, if the case has been neglected until pelvic peritonitis has occurred with its tendency to adhesions and recurrence, we will save many years of suffering, if not life itself, by advising removal of the appendages after a sufficient trial has been given to conservative treatment

Frequently in the puerperal state we have a pelvic peritonitis arise without affecting the tubes, the inflammation spreading directly through the uterus , there is an exudate formed which rest and proper treatment will absorb and leave the appendages strong and healthy, so that later pregnancy takes place and the patient goes on to full term In these cases, if suppuration occur, laparotomy should be advised In tubercular salpingitis the question of removal will depend wholly upon the amount of general systemic infection The author believes that nearly all suppurative diseases of the tubes and ovaries are due to gonorrhea, his experience leading to this belief The doctor closed with a few words on the value of electricity in the treatment of inflammations of the uterus and appendages He values this very highly, and in the catarrhal forms of endometritis in young girls and primiparæ we can obtain a cure if sufficient time is given He applies the positive pole intra-uterine, and the negative in the form of a broad electrode over the whole abdominal region, using a strength of from 20 to 50 milliamperes for five minutes every third day It requires from fifteen to twenty applications to complete a cure

XERODERMA PIGMENTOSUM

Dr A W Brayton of Indianapolis, presented two cases of Kaposi's disease—xeroderma pigmentosum—occurring in the same family The patients are girls, 2½ and 18 years old respectively A brother died of the disease at 9 years of age There are four brothers unaffected All three were affected from the fifth month of infancy Dr Wm S Corlett of Cleveland commented on the cases, of which but fifteen are known in the United States The older girl is kept comfortable by scraping out the tumors upon the hands and face as they appear A tumor the size of a hickory nut upon the eyelid Dr Corlett advised to be removed by electrolysis A lithograph and description of this case was published in the *Journal of Cutaneous and Venereal Diseases* for April, 1892 Dr Brayton also presented a case of non-pigmented sarcoma of the face in a woman 28 years old. The lesions were on the right side of the face, and varied in size from one-eighth to an inch in diameter The larger ones had been destroyed by electrolysis, but returned The growths probably originated from an infantile nævus The microscopic sections accompanying the case showed it to be small celled sarcoma The growths were painful, but not ulcerating, and there is so far no metastasis Dr A Ravogli saw and commented upon this case

Another case also examined by Dr Wm S Corlett was of idiopathic pigmented sarcoma cutis of twenty five years' standing in the person of a physician 75 years of age The growth began below the external malleolus of the left foot After ten years the whole left leg was involved, and five years later the right leg, the left arm and external margin of right ear The tumors vary from the size of a wheat grain to that of a silver dollar and are little elevated above the skin They undergo involution after four or five years, leaving well marked cicatrices This case was also commented on by Dr Corlett It belongs to the extremely rare growth (multiple pigmented sarcoma cutis of Kaposi) described by Dr J A Fordyce in the *Journal of Cutaneous* *and Venereal Diseases*, January, 1891 Dr W A Hardaway reports a case which underwent complete involution after sixteen years, leaving merely an atrophic condition of the skin In the present case the tumors, at first soft, become fibrous and disappear, leaving scars Upon the legs nearly the entire area is involved The health is good The microscope confirms the diagnosis Taylor reports a similar case of this rare affection

A case of lupus mutilons (Hutchinson) in a colored girl 8 years old, existing from infancy, was also shown The entire left arm was scarred by the disease, one finger was diseased to the bone, the thumb was stunted by the disease Dr Corlett remarked of this case that if he had seen it in Cuba he should have regarded it on first sight as a case of leprosy, so closely did the lesions simulate that disease

Section on General Surgery

Dr W N Wishard of Indianapolis, Chairman

The first paper in this Section was read by **Dr H W Loeb** of St Louis, entitled,

SOME ILLUSTRATIVE CASES OF NASAL HEADACHE

The author at the last meeting of the Missouri State Medical Association presented a paper upon nasal headaches in which the following list of such conditions was suggested as possessing an etiological significance in this regard acute inflammations of the nasal mucous membrane, chronic rhinitis, rhinoliths and foreign bodies, septal deformities, deflections, spurs, ridges, diseases of the accessory sinuses, chronic atrophic rhinitis and anything which causes the middle turbinated tissues to press against the septum In headaches of the following characters it was stated that a nasal origin might be expected 1, frontal headaches, 2, hemicrania, starting about the orbit, 3, long continued headaches, 4, headaches of which successive attacks are identical or similar, 5, headaches increased or originated by acute rhinitis, 6, headaches associated with evident disease of the nose or accessory cavities In the present paper the author presented cases which illustrated the characteristics, both symptomatic and causal, as stated in the before mentioned contribution

Dr B Merrill Ricketts of Cincinnati reported several interesting surgical cases, and exhibited photographs of the same

Dr J T Berghoff of St Joseph, Mo, read a paper entitled,

TREATMENT OF FRACTURES OF THE LEG

In treating fractures of the leg, the author said the latter should never rest on the bedding but should be suspended He cares not how well the surgeon may coaptate the broken bone and protect the same with bandages or plaster-of-paris, if the limb rest on the bedding, by each movement of the body of the patient the fracture is bound to move The process of repair is exactly the same in soft tissues and bones Why do we have union by first intention? Because we coaptate the wounds exactly, and keep them so The wound heals sometimes in three days, at the farthest a week But to put the broken limb in an immovable condition and keep it so without great suffering to the patient can not be done under the old system Dr Berghoff then described an apparatus or splint, the outgrowth of patient study for twenty years, but more particularly the last ten years The apparatus is also adapted for treating disease of the hip, knee and ankle joints as the extension can be adjusted as the case requires, the joints being kept immobile

INCURABILITY OF ADVANCED AND EXTREME CASES OF TALIPES EQUINO-VARUS BY THE MEANS AND METHODS IN VOGUE AT THE PRESENT TIME, SUGGESTION OF A WAY TO REMOVE THE DEFORMITY WITHOUT DISTURBING THE USEFULNESS OF THE EXTREMITY

The author of this paper, **Dr Louis Bauer** of St Louis, presented a plaster cast of a talipes equino-varus in which the weight of the body rested upon the dislocated astragalus and calcaneum He produced also the skeleton of a leg and foot of a person who died while in this condition He showed that there was complete dislocation of the astragalus, that the knee joint surfaces had formed between that bone and the calcaneum, whereby the weight of the body rested entirely upon the end of the astragalus and calcaneum, that the scaphoid and other bones of the foot bore little if any part in sustaining the weight of the body It has been found impossible in extreme cases of talipes to restore the foot to its natural position by tenotomy or by *brisement force* In one case, after six years' trial, the doctor had proposed an amputation similar to Chopart whereby all bones anterior to the astragalus were removed The operation would leave a linear scar anterior to the astragalus in its new position and would be out of the way, and in such direction the artificial foot could be easily adjusted He had not had an opportunity of trying this method, but felt sure that this amputation was a proper method in those cases where, after long continued efforts, reduction could not be effected He also reported a case where there was extreme lateral curvature of the spine from distortion of the pelvis in a young musician He became satisfied that the deformity was due to the unnatural position, and therefore directed a long splint applied reaching from the axilla to the foot and the pelvis was gradually pressed toward the splint by an appropriate bandage After a period of time, not stated by the speaker, the patient recovered

In the discussion which followed **Dr Marsee** of Indianapolis, took strong ground against tenotomy, tarsectomy, or amputation in these cases holding the position that by *brisement force* with a wrench or club foot stretcher he could bring the most refractory case into normal position

Dr Wm E Wirt of Cleveland, believes in resection of some of the bones after the method of Phelps in cases where tenotomy or linear osteotomy had proved unavailable

Dr John B Hamilton of Chicago, agreed with Dr Marsee in recommending the use of a club foot stretcher or wrench He would not hesitate to apply a force sufficient to comminute the dislocated astragalus if it were necessary to put the foot in position He had seen no bad results following osteoclasis The difference between osteoclasis, osteotomy or tarsectomy is precisely that between a simple and open fracture In regard to abrasions of the skin, he had not met with any, and strongly preferred osteoclasis

Dr Allan DeVilbiss of Toledo, Ohio, read a paper entitled,

NEW DEVICES FOR CUTTING BONE

Dr DeVilbiss exhibited a surgical motor with various forms of saws and drills, which he developed through a series of practical tests He had used them first upon the dead, afterwards upon the living These instruments were adapted for operation upon the skull, maxillary bone, ribs, nasal bones etc

Dr William E Wirt of Cleveland, Ohio, read a paper on

THE TREATMENT OF OLD CASES OF HIP DISEASE

He said there is no doubt that if convalescent cases of hip disease were carefully and persistently treated during a long period of complete recovery, whatever deformity had existed up to this time and that which accompanies this period, could be entirely overcome without operation When shall a case of hip disease be considered to have progressed far enough to permit the removal of the extension splint and the substitution of a convalescent brace? The solution of this problem was a matter of judgment It is better to allow the extension splint to be worn unnecessarily long than for the substitution to be made too soon

The deformities requiring correction are flexion and adduction Dr Wirt had been surprised in several instances of old cases of hip disease with considerable deformity where, after the application of continuous extension in bed for a few weeks the deformity would be considerably reduced After a trial of extension in bed with a failure to reduce deformity there remains as a means of correction 1, brisement force, with or without myotomy, tenotomy, faciotomy, etc , 2, osteoclasis, 3, osteotomy These operations were then considered by the author under their respective heads Osteoclasis and osteotomy are reserved for those cases in which there exists bony union or a fibrous ankylosis of a very firm character The author reported sixteen cases following Grant's operation

A CASE OF SENILE GANGRENE TREATED BY AMPUTATION

This paper was contributed by **Dr G W H Kemper** of Muncie, Ind The patient was a farmer aged 73 years After detailing the particulars of the case the author drew the following deductions

1 —While the gangrene is confined to one or two toes, it is best to defer amputation If the disease extends to the dorsum of the foot amputation is proper

2 —Amputation below the knee is rarely successful, owing to lack of proper blood supply and tendency to recurrence of gangrene in the stump

3 —Amputation through the thigh will save a large per cent of the cases, and especially so when the subjects are free from a general disease Maunsell-Moullin observes that usually the thigh is small and wasted in the lower

third, the artery is sound in Hunter's canal, the flaps are well supplied with blood, and old people as a rule resent operation very slightly Their tissues are not prone to inflammation

4—When amputation has been performed below the knee, and gangrene appears in the stump, unless the patient is exhausted, it will be proper to perform a secondary amputation above the knee

Dr I N Quimby of Jersey City, N J, read a paper entitled,

A NEW METHOD OF OPERATING AT THE ANKLE JOINT FOR INJURIES OF THE FOOT

The method consists of making a curvilinear incision across the dorsum of the foot, commencing anterior to and a little below the internal malleolus, and terminating at a corresponding point a little below the external malleolus, and then uniting the two extremities of the dorsal section by an incision across the sole of the foot, forming an anterior and posterior flap similar to the operation performed by Pirogoff of Russia After forming a short anterior flap and turning it back, he then dissects out the astragalus from its attachments, being careful to keep close to the bone, then forming a linear posterior flap from the sole of the foot he makes a careful dissection, exposing the anterior half of the calcaneum This being done, and the soft parts being well retracted by an assistant, the saw is applied so as to remove nearly the anterior half of the bone by an incision from above downward and from behind forward The sharp edges of the remaining portion of the bone are then rounded off and the sawed surface is applied directly to the articular surface of the tibia between the malleoli, without removing any part of the cartilaginous surface After stitching up the flap in the usual way a strap of adhesive plaster is applied three or four inches in width extending from the upper portion of the gastrocnemius muscle to a corresponding point on the anterior surface of the leg passing directly over the os calcis, so as to keep closely and firmly in apposition to the articular surface of the tibia, which is kept there until the union of bones has taken place

THE BACTERIA OF THE SURFACE

Dr Frank J Thornbury of Buffalo, read a paper under this title in which the latest researches were set forth, rational mechanical means of disinfection summarized, and the non-utility of antiseptics proclaimed The varieties of organisms which the cutaneous and mucous surfaces present in great abundance comprise molds, yeast fungi, bacilli, cocci, color and odor-producing bacteria The hairy regions, as the axillary space, and the interdigital folds are the places of predilection for the bacteria upon the cutis Myriads of microbes are present in the oral cavity, the intestinal tract, the genital tract of the female, the male urethra, and in the conjunctival secretion and cerumen of the ear Among the masses are germs which are pathogenic, as the Fehleisen streptococcus of erysipelas The cleansing of the surface constitutes one of the most important duties of asepsis This pertains especially to the physician's own hands The disinfection can not be accomplished by the use of antiseptics, so called, which do not even reach the bacteria imbedded in the substrata of fat and dirt The disinfection must be mechanical, dissolving away the glandular secretions, dead epidermal cells vegetable and albuminous substances For the latter purpose soap, hot water and brush are used, aided by alcohol and ether, and rubbing with sterile towels Baths are an important adjunct to asepsis and one or a number should be administered previous to operation

THE ETIOLOGY, DIAGNOSIS AND TREATMENT OF ULCERATION OF THE RECTUM

This subject was dealt with in a general way by **Dr Joseph M Matthews** of Louisville As a matter of convenience he classified these ulcers under four heads benign, malignant, tubercular and specific He said to this division there might be a valid objection based upon correct pathological grounds For instance, in this classification he makes the term, malignant, synonymous with cancer, and yet the tubercular ulcer may in truth be malignant without assuming the characteristics of cancer Again some writers would have us believe that a tuberculous patient is closely akin at least to a syphilitic one or vice versa Benign ulceration is not so frequently found in the rectum as is supposed Whenever the author meets with a well-defined ulceration existing in the rectum, he immediately begins to suspect some special diathesis It is only when the facility of defecation is interfered with that any danger is to be feared The lumen of this portion of the gut is not narrowed by any ordinary causes For these and other causes Dr Matthews has long since been forced to believe that such ascribed causes as pregnancy, dysentery, etc, were not great factors in producing ulceration of the rectum The speaker then dwelt upon malignant ulceration of the rectum, saying that is a favorite seat for cancer Many times the disease is overlooked entirely or diagnosticated as some other affection It has occurred to him several times to have had patients referred to him for some trivial rectal trouble and found cancer instead The more he practices the more he is convinced that syphilis is responsible for fully one-half of the cases of severe ulceration of the rectum The treatment must in every individual case depend upon the known character of it We can not treat a benign ulcer as we would a malignant one, nor a tubercular ulcer as a specific one, nor the last named as the first named Benign growths of the rectum require local applications Malignant, extirpation tuberculous, the curette, syphilitic, anti-syphilitic and local medication, extirpation, colotomy

INGUINAL COLOTOMY

Dr Leon Straus of St Louis, read a paper with this title, in which he entered a plea for more frequent and earlier colotomy in painful malignant diseases of the rectum Dr. Straus stated his reasons for making colotomy as follows 1, it is the greatest modern surgical relief measure, inasmuch as it completely does away with the function of the rectum, thereby relieving the intense pain caused by defecation Pain is an inevitable result in advanced malignant disease of the rectum There are few exceptional cases which only prove the rule, 2, the lease of life is extended There are many instances where it has been considerably extended So great authorities as Cripps, Allingham, and Eiselsberg claim to have extended the lease for weeks or months Are not these most cogent reasons for making a colotomy? 3, the risk of the operation has been minimized Allingham has made sixty eight colotomies with only two deaths, and they were total obstruction cases Cripps forty-eight with one death, this was a total obstruction case Edwards has made sixteen, with one death The patient was very septic at the time of operation Reeves has made sixty-five operations without a death Goodsall has made twenty-two without a death Statistics show a death rate of less than 2 per cent By making early colotomy the author believes that the death rate might be reduced to less than 1 per cent

Dr Wm Thos Corlett of Cleveland, Ohio, read a paper on

THE CLINICAL VARIETIES AND TREATMENT OF PEMPHIGUS

His paper was illustrated by the description of unusual cases The writer divided pemphigus into two main varieties, *pemphigus vulgaris* and *pemphigus foliaceus*, under which all cases, although differing in certain features, may be grouped Under acute pemphigus he gave the history of an epidemic of pemphigus in the newborn The main features were that all the cases occurred in the practice of one midwife, the disease began at the end of the first week, as an erythema on the lower part of the face, or upper part of the chest This was followed by the formation of blebs with flabby walls which soon ruptured leaving extensive raw surfaces About three fourths of the body was involved and terminated fatally about the tenth day The writer regarded it as due to contagion

Under chronic pemphigus, which is the most common form, Dr Corlett drew attention to the frequency with which the mucous membranes were involved and cited a case in which the disease first appeared in the bronchial tubes simulating capillary bronchitis Later it appeared in the mouth and throat, which from its resemblance to diphtheria has been called pemphigus diphtheriticus Finally the disease attacked the eyeballs On the skin it differed in no way from the usual form The case ended in recovery, but with the complete loss of sight

In the treatment, he thought arsenic had been over estimated Iron strychnin and arsenic benefited only as general tonics which were especially indicated in this disease Locally the continuous tepid bath was recommended, but unfortunately it is often impracticable when recourse must be had in simpler measures As soothing applications, the glycerol of tannin, one part to three or four of distilled hamamelis, or water, or the glycerol of lead, one ounce to a pint of water, he thought the best at our command The latter was preferred when but small areas were denuded of epidermis When itching is present a 3 per cent solution *and Venereal Diseases*, January, 1891 Dr W A Hardaway reports a case which underwent complete involution after sixteen years, leaving merely an atrophic condition of the skin In the present case the tumors, at first soft, become fibrous and disappear, leaving scars Upon the legs nearly the entire area is involved The health is good The microscope confirms the diagnosis Taylor reports a similar case of this rare affection

A case of lupus mutilons (Hutchinson) in a colored girl 8 years old, existing from infancy, was also shown The entire left arm was scarred by the disease, one finger was diseased to the bone, the thumb was stunted by the disease Dr Corlett remarked of this case that if he had seen it in Cuba he should have regarded it on first sight as a case of leprosy, so closely did the lesions simulate that disease

Dr Leon Straus of St Louis, read a paper with this title, in which he entered a plea for more frequent and earlier colotomy in painful malignant diseases of the rectum Dr Straus stated his reasons for making colotomy as follows 1, it is the greatest modern surgical relief measure, inasmuch as it completely does away with the function of the rectum, thereby relieving the intense pain caused by defecation Pain is an inevitable result in advanced malignant disease of the rectum There are few exceptional cases which only prove the rule, 2, the lease of life is extended There are many instances where it has been considerably extended So great authorities as Cripps, Allingham, and Eiselsberg claim to have extended the lease for weeks or months Are not these most cogent reasons for making a colotomy? 3, the risk of the operation has been minimized Allingham has made sixty eight colotomies with only two deaths, and they were total obstruction cases Cripps forty-eight with one death, this was a total obstruction case Edwards has made sixteen, with one death The patient was very septic at the time of operation Reeves has made sixty-five operations without a death Goodsall has made twenty-two without a death Statistics show a death rate of less than 2 per cent By making early colotomy the author believes that the death rate might be reduced to less than 1 per cent

Dr Wm Thos Corlett of Cleveland, Ohio, read a paper on

THE CLINICAL VARIETIES AND TREATMENT OF PEMPHIGUS

His paper was illustrated by the description of unusual cases The writer divided pemphigus into two main varieties, *pemphigus vulgaris* and *pemphigus foliaceus*, under which all cases, although differing in certain features, may be grouped Under acute pemphigus he gave the history of an epidemic of pemphigus in the newborn The main features were that all the cases occurred in the practice of one midwife, the disease began at the end of the first week, as an erythema on the lower part of the face, or upper part of the chest This was followed by the formation of blebs with flabby walls which soon ruptured leaving extensive raw surfaces About three fourths of the body was involved and terminated fatally about the tenth day The writer regarded it as due to contagion

Under chronic pemphigus, which is the most common form, Dr Corlett drew attention to the frequency with which the mucous membranes were involved and cited a case in which the disease first appeared in the bronchial tubes simulating capillary bronchitis Later it appeared in the mouth and throat, which from its resemblance to diphtheria has been called pemphigus diphtheriticus Finally the disease attacked the eyeballs On the skin it differed in no way from the usual form The case ended in recovery, but with the complete loss of sight

In the treatment, he thought arsenic had been over estimated Iron, strychnin and arsenic benefited only as general tonics which were especially indicated in this disease Locally the continuous tepid bath was recommended, but unfortunately it is often impracticable when recourse must be had in simpler measures As soothing applications, the glycerol of tannin, one part to three or four of distilled hamamelis or water, or the glycerol of lead, one ounce to a pint of water, he thought the best at our command Th[illegible] latter was preferred when but small areas were denude[illegible] epidermis When itching is present a 3 per cent so of resorcin was recommended Finally when desquamation sets in some emollient, such as the zinc ointment or carbolized vaselin will afford the best relief

KRASKE'S OPERATION WITH REPORT OF CASES

By Dr H O Walker of Detroit, Mich The author of this paper said that a man or woman who had cancer of the rectum was of few days, and the method of relief could be done in three ways—either by proctotomy and scooping away of the growth, by excision of the cancer, or by colotomy, all of which were temporary, as the author had never seen a case of true cancer that ever got well When the malignant growth was high up, say two or three inches above the rectum, the best operation to make would be by Kraske's method, that is, by making an incision down through the second sacral vertebra to the anus to the left of the coccyx, and rapidly stripping off the muscular and ligamentous attachments to the coccyx and cutting them away with the bone forceps and as much of the sacrum as is necessary to expose the growth Then we have a full view for enucleating the growth and excising it It is well known that it is a difficult matter to approximate the ends by suture method, and an idea was forced upon Dr Walker from his knowledge of the Murphy button that with a large button, say two inches in diameter, which he exhibited to the Association, he could approximate the cut ends of the rectum, and by this means prevent the infiltration of fecal matter to approximate the ends by suture method and an idea was forced upon Dr Walker from his knowledge of the Murphy button that with a large button, say two inches in diameter, which he exhibited to the Association, he could approximate the cut ends of the rectum, and by this means prevent the infiltration of fecal matter, which by the other method was an impossibility In this connection, Dr Walker said he had made the first end-to-end approximation by the Murphy button in a case of fecal fistula on the 8th of December, and the patient on whom he had operated made a good recovery and within two weeks was as well as ever, with no evidence of any contraction of the intestine

SOME HERESIES REGARDING PROSTATIC PATHOLOGY

This paper was contributed by Dr G Frank Lydston of Chicago The author said among the many ills which were marked noli me tangere until recent years, and which modern surgery has done much to relieve, prostatic hypertrophy occupies a very prominent position The surgical resources at present at our command were then briefly stated The author is becoming daily more and more firmly convinced that the ideal operation is a combined suprapubic and perineal section performed at an early period He believes that in many cases this early operation will not only forestall circumscribed prostatic obstructions, median or lateral, but will prove directly curative by restoring the normal function of micturition Supra-pubic cystotomy is undoubtedly the best method of draining the bladder, as far as a single operation is concerned, and in many instances it is all sufficient When combined, however, with perineal section, prostatic dilatation and prolonged drainage by a large tube, we often do away with certain conditions which exist in the way of contracted lumen of the prostatic urethra and hyper excitability of this portion of the urinary tract, which supra pubic cystotomy alone might not accomplish

Dr Lydston believes that the main factors in the etiology of prostatic disease are laid down in many cases, if not the majority, before middle life

The surgical address before the general session was given by Dr Henry O Marcy of Boston, the subject having been selected by a request, as that of

INGUINAL HERNIA, ITS ANATOMY AND BETTER METHODS FOR CURE

Dr Marcy illustrated his lecture by a series of slides reproducing the magnificent illustrated work of the old masters—Kamper, Cooper, Scarpi, Bougerey, and others By general consensus of opinion the profession is indebted to Dr Marcy as an innovator in this field of labor He had established the value of the buried animal suture and published his results quite five years before that of Weith of Germany, to whom in Europe the credit is generally attributed The essential principles of his operation for hernia have become universally accepted The result of the work of a large number of the modern operators give from 70 to 90 per cent of permanent cures In resumé, Dr Marcy claims that the peritoneal sac as a rule should be resected after suturing quite to its very base, that the deeper structures which go to make up the posterior wall of the inguinal canal should be reinforced and restored to their original normal condition, that the external wound should be closed without drainage and the skin wound sealed with iodoform collodion In his large experience involving several hundred cases, he states that where the intestine has not been involved from strangulation or other cause, not one of his patients has appeared to approach the danger line, and that of the entire number which he has been able to trace, more than 90 per cent have remained after one year permanently cured

Papers were also read before this section by Drs William N Wishard of Indianapolis, J McLean Moulder of Kokomo, Ind, William T Belfield of Chicago, and others

Committee on Nominations organized by election of Dudley S Reynolds of Louisville, chairman and I N Love, secretary

The following officers were elected for the ensuing year

President—Dr X C Scott of Cleveland, Ohio
First Vice President—Dr Leon Straus of St Louis
Second Vice-President—Dr G Frank Lydston of Chicago
Secretary—Dr Frederick C Woodburn of Indianapolis
Treasurer—Dr George J Cook of Indianapolis
Chairman Com of Arrangements—Dr Thos E Holland of Hot Springs

Hot Springs, Ark, was selected as the next place of meeting Time of meeting, first Tuesday in November

After drafting and adopting resolutions of thanks, the Association adjourned

---

Tri-State Medical Association—The Tri-State Medical Association of Arkansas, Tennessee and Mississippi will convene in annual session in Memphis, Tenn, on Nov 22 and 23, 1893

Members of the Association and all regular physicians in good standing are cordially invited to attend

Those intending to contribute papers or report cases of importance occurring in their practice, should notify the Secretary at once, giving title of paper, in order that their names may appear on the program A L Elcan, M D

Secretary, Memphis, Tenn

West Tennessee Medical and Surgical Association will meet at Brownsville, Tenn, Thursday, October 26, at 2 30 p m A session will be held also at night and one on Friday morning, the 27th This arrangement is made to save time, and to avoid night travel Dr I A McSwain is the Secretary

---

Mississippi Valley Association Notes—The *Indiana Medical Journal* will in its next issue print the proceedings in full Among the medical editors present we noticed Dr R B Granger of the *New York Medical Journal*, Dr Brayton of the *Indiana Medical Journal*, Dr Culbertson of the *Lancet and Clinic*, Dr I N Love of the *Medical Mirror* of St Louis, Dr G F Lydston of the *Western Medical Reporter* and Dr John B Hamilton of this Journal Dr James F Hibberd the President-elect of the American Medical Association gave the annual address in medicine The reception was held at the Denison House, and Governor Matthews honored the occasion by his presence The Chairman of the Committee of Arrangements, Dr Cook, and the secretary of the Association, Dr Woodburn, have reason to be gratified at the success of the meeting

ASSOCIATION NEWS

The Journal of the American Medical Association —"Since the meeting of the Medical Association at Milwaukee, we have watched this journal with unusual interest, because its new editor was not only so well known to the profession at large, but also because he came from our own city, and, therefore any success he might achieve would reflect, so we argued, credit upon the city from which he came That Dr Hamilton has fulfilled the highest expectations of his friends goes without saying The profession should take great pride in making this journal its representative both at home and abroad We are equal in every way to our friends across the water, and there is no reason why, in the matter of a representative journal, we should not certainly equal, if not excel them That the JOURNAL will do this under the editorial management of Dr Hamilton we firmly believe But he must be supported, of course, by the whole profession This can not be done in any better way, than by sending the annual subscription of $5 00 to the JOURNAL, at 68 Wabash Avenue, Chicago"—*Food*, October,1893

NECROLOGY

Dr Edward Warren Bey, whose death has recently been announced, has for nearly twenty years been one of the leading physicians of Paris, and of world wide reputation He was born in Tyrrell County, North Carolina, Jan 22, 1828 His parents were natives of Virginia His father, Dr Wm C Warren was a man of intelligence and good professional attainments When the subject of this sketch was but 4 years of age his father removed with his family to Edenton, N C When of a proper age the boy was sent to the Fairfax Institute, near Alexandria, where he remained for two years, and was then placed at the University of Virginia, where he won honors and received diplomas, and by selection delivered the valedictory before the Jefferson Society In 1851 he graduated from the Jefferson Medical College in Philadelphia

It is stated by one of his biographers that while pursuing his studies in Philadelphia he conceived the idea of administering morphin under the skin for the relief of pain by puncture with Anel's syringe He had written his thesis for graduation on this method of administering medicines, but mentioning it to one of the faculty, who looked upon it as chimerical and dangerous, he was dissuaded from presenting the paper and wrote one on another subject He had, however, become so thoroughly convinced of the practicability of the method that he soon after put it to a practical test, and was some four years in advance of the public announcements of this very useful method of administering remedies

To farther prosecute his medical studies he spent most of the years 1854 and 1855 in attending the hospitals and clinics of Paris, and during this time formed strong and lasting friendships with many of the leading medical men of France He was a ready and a graceful writer, and contributed from the French capital a number of very acceptable articles to the *American Journal of Medical Sciences* and to other American medical publications

On returning to the United States he settled to practice in Edenton, N C He was thoroughly well equipped to practice medicine and speedily acquired a leading position among the medical men of the region In 1856 he was selected to deliver the annual address before the State Medical Society, which was well received and brought him prominently before the active workers in the professional ranks The same year he obtained the "Fish Fund Prize" for an essay on the "Effects of Pregnancy on the developing of Tuberculosis" This paper has passed into the permanent literature of medicine In 1857 he was elected editor of the *North Carolina Medical Journal*, at the time the official organ of the State Medical Society The Gynecological Society of Boston the same year elected him a member While in Paris he became a member of the "American Medical Society of Paris," and this organization sent him as their delegate to the American Medical Association, but he was unable to attend or register But he was a delegate from the State Medical Society of North Carolina to the meeting of the American Medical Association at Louisville, Ky, in 1859 He also attended meetings from Baltimore, Md, where he was then practicing, in 1860, 1866, 1868, 1870 and 1872

Dr Warren was on Nov 16, 1857 united in marriage to Miss Elizabeth Cotton Johnston of Edenton, a most estimable lady whose ancestors were extensively connected with many distinguished families in the old North State and in Virginia

Dr Warren's reputation for learning and scientific acquirements had become so widely known in 1860, that he was elected professor of materia medica and therapeutics in the old and prosperous University of Maryland This led to his removal to the city of Baltimore The same year he was elected the first vice-president of the convention for the revision of the United States Pharmacopeia In the University of Maryland he at once took high rank as an able teacher and an attractive lecturer

On the breaking out of the war between the States he threw his fortunes with his native State and his friends in the South He served in the field, in hospitals and on medical boards He was chief surgeon in the North Carolina of resorcin was recommended Finally when desquamation sets in some emollient, such as the zinc ointment or carbolized vaselin will afford the best relief

KRASKE'S OPERATION WITH REPORT OF CASES

By Dr H O Walker of Detroit, Mich The author of this paper said that a man or woman who had cancer of the rectum was of few days, and the method of relief could be done in three ways—either by proctotomy and scooping away of the growth, by excision of the cancer, or by colotomy, all of which were temporary, as the author had never seen a case of true cancer that ever got well When the malignant growth was high up, say two or three inches above the rectum, the best operation to make would be by Kraske's method, that is, by making an incision down through the second sacral vertebra to the anus to the left of the coccyx, and rapidly stripping off the muscular and ligamentous attachments to the coccyx and cutting them away with the bone forceps and as much of the sacrum as is necessary to expose the growth Then we have a full view for enucleating the growth and excising it It is well known that it is a difficult matter to approxmate the ends by suture method, and an idea was forced upon Dr Walker from his knowledge of the Murphy button that with a large button, say two inches in diameter, which he exhibited to the Association, he could approximate the cut ends of the rectum, and by this means prevent the infiltration of fecal matter to approximate the ends by suture method and an idea was forced upon Dr Walker from his knowledge of the Murphy button that with a large button, say two inches in diameter, which he exhibited to the Association, he could approximate the cut ends of the rectum, and by this means prevent the infiltration of fecal matter, which by the other method was an impossibility In this connection, Dr Walker said he had made the first end-to-end approximation by the Murphy button in a case of fecal fistula on the 8th of December, and the patient on whom he had operated made a good recovery and within two weeks was as well as ever, with no evidence of any contraction of the intestine

SOME HERESIES REGARDING PROSTATIC PATHOLOGY

This paper was contributed by Dr G Frank Lydston of Chicago The author said among the many ills which were marked noli me tangere until recent years, and which modern surgery has done much to relieve, prostatic hypertrophy occupies a very prominent position The surgical resources at present at our command were then briefly stated The author is becoming daily more and more firmly convinced that the ideal operation is a combined suprapubic and perineal section performed at an early period He believes that in many cases this early operation will not only forestall circumscribed prostatic obstructions, median or lateral, but will prove directly curative by restoring the normal function of micturition Supra-pubic cystotomy is undoubtedly the best method of draining the bladder, as far as a single operation is concerned, and in many instances it is all sufficient When combined, however, with perineal section, prostatic dilatation and prolonged drainage by a large tube, we often do away with certain conditions which exist in the way of contracted lumen of the prostatic urethra and hyper excitability of this portion of the urinary tract, which supra pubic cystotomy alone might not accomplish

Dr Lydston believes that the main factors in the etiology of prostatic disease are laid down in many cases, if not the majority before middle life

The surgical address before the general session was given by Dr Henry O Marcy of Boston, the subject having been selected by a request, as that of

INGUINAL HERNIA, ITS ANATOMY AND BETTER METHODS FOR CURE

Dr Marcy illustrated his lecture by a series of slides reproducing the magnificent illustrated work of the old masters—Kamper, Cooper, Scarpi, Bougerey, and others By general consensus of opinion the profession is indebted to Dr Marcy as an innovator in this field of labor He had established the value of the buried animal suture and published his results quite five years before that of Weith of Germany, to whom in Europe the credit is generally attributed The essential principles of his operation for hernia have become universally accepted The result of the work of a large number of the modern operators give from 70 to 90 per cent of permanent cures In resumé, Dr Marcy claims that the peritoneal sac as a rule should be resected after suturing quite to its very base, that the deeper structures which go to make up the posterior wall of the inguinal canal should be reinforced and restored to their original normal condition, that the external wound should be closed without drainage and the skin wound sealed with iodoform collodion In his large experience involving several hundred cases, he states that where the intestine has not been involved from strangulation or other cause, not one of his patients has appeared to approach the danger line, and that of the entire number which he has been able to trace, more than 90 per cent have remained after one year permanently cured

NECROLOGY

Dr Edward Warren Bey, whose death has recently been announced, has for nearly twenty years been one of the leading physicians of Paris, and of world wide reputation He was born in Tyrrell County, North Carolina, Jan 22, 1828 His parents were natives of Virginia His father, Dr Wm C Warren was a man of intelligence and good professional attainments When the subject of this sketch was but 4 years of age his father removed with his family to Edenton, N C When of a proper age the boy was sent to the Fairfax Institute, near Alexandria, where he remained for two years, and was then placed at the University of Virginia, where he won honors and received diplomas, and by selection delivered the valedictory before the Jefferson Society In 1851 he graduated from the Jefferson Medical College in Philadelphia

It is stated by one of his biographers that while pursuing his studies in Philadelphia he conceived the idea of administering morphin under the skin for the relief of pain by puncture with Anel's syringe He had written his thesis for graduation on this method of administering medicines, but mentioning it to one of the faculty, who looked upon it as chimerical and dangerous, he was dissuaded from presenting the paper and wrote one on another subject He had, however, become so thoroughly convinced of the practicability of the method that he soon after put it to a practical test, and was some four years in advance of the public announcements of this very useful method of administering remedies

To farther prosecute his medical studies he spent most of the years 1854 and 1855 in attending the hospitals and clinics of Paris, and during this time formed strong and lasting friendships with many of the leading medical men of France He was a ready and a graceful writer and contributed from the French capital a number of very acceptable articles to the *American Journal of Medical Sciences* and to other American medical publications

On returning to the United States he settled to practice in Edenton, N C He was thoroughly well equipped to practice medicine and speedily acquired a leading position among the medical men of the region In 1856 he was selected to deliver the annual address before the State Medical Society, which was well received and brought him prominently before the active workers in the professional ranks The same year he obtained the ' Fish Fund Prize" for an essay on the "Effects of Pregnancy on the developing of Tuberculosis" This paper has passed into the permanent literature of medicine In 1857 he was elected editor of the *North Carolina Medical Journal*, at the time the official organ of the State Medical Society The Gynecological Society of Boston the same year elected him a member While in Paris he became a member of the "American Medical Society of Paris," and this organization sent him as their delegate to the American Medical Association, but he was unable to attend or register But he was a delegate from the State Medical Society of North Carolina to the meeting of the American Medical Association at Louisville, Ky, in 1859 He also attended meetings from Baltimore, Md, where he was then practicing, in 1860, 1866, 1868, 1870 and 1872

Dr Warren was on Nov 16, 1857 united in marriage to Miss Elizabeth Cotton Johnston of Edenton, a most estimable lady whose ancestors were extensively connected with many distinguished families in the old North State and in Virginia

Dr Warren's reputation for learning and scientific acquirements had become so widely known in 1860, that he was elected professor of materia medica and therapeutics in the old and prosperous University of Maryland This led to his removal to the city of Baltimore The same year he was elected the first vice president of the convention for the revision of the United States Pharmacopeia In the University of Maryland he at once took high rank as an able teacher and an attractive lecturer

On the breaking out of the war between the States he threw his fortunes with his native State and his friends in the South He served in the field, in hospitals and on medical boards He was chief surgeon in the North Carolina

Navy and medical director of the Cape Fear section He was also for a time the chief medical inspector of the Department of Northern Virginia He was twice promoted for his efficiency and courage on the field of battle This trait of efficiency in the doctor was so notable as to attract attention, and the fact coming to the attention of the Assembly of North Carolina, an Act was passed by them raising his rank from that of colonel to that of brigadier general for "efficient services rendered to sick and wounded"

Notwithstanding the engrossing official and professional duties of Dr Warren during the war, he wrote a work to meet the needs of surgeons in the field, entitled, "Surgery for Field and Hospital" In this publication, which was well received and speedily passed through two editions, the doctor made some valuable original suggestions In 1865, Dr Warren resumed his residence in Baltimore, expecting at the same time to resume his professional duties in the University of Maryland But the changed conditions of the country and the status of the Southern States, the policy of the general government and local interests combined to close the doors of that institution against him

He was not only capable but ambitious and full of energy, and it was mainly at his suggestion and through his efforts that the old Washington University Medical School was revived and rapidly rose to have a commanding position and an able faculty and good patronage In this faculty Dr Warren filled most acceptably the chair of surgery

When the Act of Assembly of Maryland passed requiring an examination and registration of the physicians of the State, Dr Warren was appointed upon the board to carry the law into effect

In 1868 he was elected one of the vice-presidents of the Medical and Chirurgical Faculty of Maryland, and the same year founded the *Medical Bulletin*, which under his management acquired a large circulation

The celebrated Wharton trial, which took place in 1872 brought Dr Warren to the forefront among specialists in criminal trials He was confronted by able physiologists, general practitioners and chemists and their theories and tests shown to be inconclusive The case attracted wide attention not only in America but in Europe Dr Warren ably sustained himself before the court, and his testimony so completely broke down the chemical evidence relied upon by the prosecution as to compel the court to enter a nolle prosequi in the case For some time after the doctor was made a target for critics, not only in the medical profession but by the bar and the public press But it is simple justice to say that no review of his evidence and theory of the case was ever able to demonstrate that he was in error in his views

At the meeting of the American Medical Association in 1872 he was chosen Chairman of the Section of Surgery for the following year He did not, however, attend that meeting or send a report

In 1873 Dr Warren suffered a severe domestic affliction in the death of his devoted wife His health suffered seriously and to change the scene he consented to accept a medical position in the Army of the Khedive of Egypt His service although brief in that country was nevertheless sufficiently conspicuous to place him at the head of the surgical staff It was his good fortune to relieve Kissim Pasha the Minister of War from a strangulated hernia

This operation was undertaken when the war minister's life was despaired of by his own surgeons, and when it was almost impossible for Dr Warren to get any of them to assist him in the operation from a religious dread of being blamed with causing his death But the operation was a success and the result placed the courageous Dr Warren in the front rank of surgeons in the Khedive's army

His splendid success where death was imminent and expected, induced the Khedive to confer upon Dr Warren the Decoration of the Medjidie and the title of Bey

Dr Warren unfortunately contracted a severe form of ophthalmia common in the East and it proving obstinate, he obtained a furlough for six months to visit Paris for treatment Here he was promptly told that one eye was practically lost and that a longer residence in Egypt would result in the loss of the other

He had no alternative but to resign, which he did The Khedive was most kind, and in accepting his resignation spoke of his valuable services in the Egyptian army and wished him long years of usefulness

It was then while still under treatment that he was advised to become a candidate for practice in Paris After many conferences with friends and the earnest advice of Dr Charcot, Breed and other eminent practitioners, he concluded to take up his permanent residence in Paris

Dr Warren's success in the metropolis of France was exceptionally rapid and gratifying Both practice and honors came flowing in upon him From Spain he received the decoration of a "Knight of the order of Isabella the Catholic," for earnest services rendered to Spanish subjects, and from his old Maryland a degree of "Master of Surgery"

Dr Warren both as a boy and through his life proved his indomitable energy and power of work He secured a large share of confidence with his professional brethren And yet like all men of force and original ideas, antagonisms were evolved by the friction That he was a man of ability and culture his life and works attest His house in Paris was frequented by Americans and travelers from other countries, and his attentions and hospitalities for years generously bestowed upon numerous friends visiting Paris

J M T

Dr Thomas Lincoln Richards of the Vanderbilt Clinic of New York city, died Sunday, October 1, at the age of twenty-nine years His malady, so seldom fatal among physicians, was smallpox, contracted while in the performance of his duty at the clinic A patient was under treatment for varicella by one of the staff, who exhibited the case freely as a typical case of that disease Two ph[illegible]cians were taken ill about the same date, one of [illegible] recovered and one, Dr Richards, succumbed to wh[illegible] first appeared to be a mild form of variolous disease He was an alumnus of the College of Physicians and Surgeons, New York, and an ex-interne of the Bellevue Hospital, during 1892 His former home was at Fort Atkinson, Wis It is an extremely infrequent event, so far as can be ascertained from the periodical literature of medicine, that a physician falls a victim to variola In this case of Dr Richards, the attack did not at first seem serious, neither did he seem to suffer in consequence of his removal from his home in the city to the Contagious Disease Hospital on North Brother Island, but he grew worse from day to day after his removal Dr Richards was unmarried

Dr T J Sprague of Joliet, Ill, lately appointed pension examiner, died October 3

BOOK NOTICES

System of Diseases of the Ear, Nose, and Throat Edited [illegible] Charles H Burnett A M M D Emeritus Professor of Otology in the Philadelphia Policlinic etc, Philadelphia, Pa Vol II Illustrated Philadelphia J B Lippincott Company 1853

This is an important work of 858 pages, containing six papers on diseases of the nose, and seventeen on throat affections Of the twenty-three writers New York is represented by seven, Pennsylvania four, Michigan two, and several other States by one each One foreign country, England, is also represented

The book is well illustrated with many plates and figures Some of these are exceptionally finely executed, the plates being introduced in separate sheets

W C Jarvis has a 28 page article on surgical procedures in deformities and neoplastic growths in the nose It is prepared with great care and thoroughness, and the fairness and generosity of the author are conspicuous on every page in the numerous references to other authors, and the credits duly accorded each for originality and priority in discoveries and methods

J A White gives the most elaborate elucidation of the subject of neuroses of the nose we have ever seen He devotes fifty eight pages to this topic His exposition of the nasal reflexes is clearly abreast of the times and is full of proof of extensive research The importance of recognizing and properly treating nasal reflex cough is shown in the misery and expense endured by those sufferers who are annually dragged from their homes and family ties to spend their winters in the south or the mountains of the West, only to find at last that a little judicious treatment of a nasal affection banishes the specter of phthisis

Dr White has obtained the best results in treating paroxysms of asthma, by spraying the nose with a 4 per cent solution of cocain followed by a second spray of camphor-menthol, 6 per cent Cerebral sedatives and vaso-tonics are added

A W MacCoy has a beautifully illustrated paper of twenty pages on the anatomy and physiology of the pharynx and larynx

Max Thorner has written twenty-four pages of great practical value on the various forms of acute pharyngitis He opens with an interesting discussion of the mooted question of taking cold He pays doubtful respects to the old theory, and discreetly steps out of the arena while he introduces the several disputants to fight it out among themselves His remarks on treatment embrace the most valuable of the new remedies

E F Ingals has twenty pages on chronic pharyngitis, in which no space is wasted in historic disquisition or references to other writers He records merely the results of his own observations and rich experience, in smooth, flowing English

W C Glasgow, in treating of croup, throws discredit on the time-honored remedy, calomel, for preventing the fibrinous exudate Otherwise his treatment is orthodox He indorses Dr Wetmore's iron treatment

J L Smith, in an exhaustive paper of forty seven pages on diphtheria, maintains that it is primarily a local disease of microbic origin His warnings against that undeservedly popular remedy, potassium chlorate, are telling and timely He uses H_2O_2 in 10 per cent solution for spraying the throat A good dioxid of hydrogen is neither toxic or irritating, and gives the best results in full strength No opinion is expressed in the efficacy of sulpho-calcin or methyl-violet Corrosive sublimate is recommended internally and locally, but pilocarpin is condemned

J Solis Cohen brings the volume to a close with an admirable treatment of a most difficult subject—tuberculosis and syphilis of the larynx In tuberculosis he places reliance on creosote internally, and lactic acid topically, and is opposed to the galvano cautery Twenty per cent solutions of menthol in olive oil are injected into the larynx

A Treatise on Ophthalmology for the General Practitioner Second edition, revised and enlarged, with 140 illustrations, by Adolph Alt, M D 8vo cl pp 330 St Louis J H Chambers & Co 1893

That the book was acceptable to those for whom it was intended is evident from the fact that it has now passed to its second edition It is divided into twenty-eight chapters The first gives the anatomy of the eye and its appendages, the second the method of examination Chapter six being on "Minor Manipulations in the Treatment of Eye Diseases," is dislocated by being placed between chapter five on diseases of the orbit, and chapter seven on diseases of the orbit The remarks on asepsis and antisepsis are excellent so far as care of the instruments are concerned, but a little more detailed direction of the precautions on the part of the practitioner, would have added to the value of the book While there are operations illustrated and described that the general practitioner will rarely, if ever, perform, there is so much of value that we unhesitatingly commend the work to those for whose instruction it is intended

State Medical Association of Texas —Transactions for 1893 This volume includes the report of the transactions of the twenty-fifth annual meeting, which was held at Galveston in May, 1893 There are several notable papers in the transactions, and no pains have been spared apparently to render the book typographically the equal of other State transactions A glance at the papers shows them to be complete, and at the same time not so "long drawn out" as to be tedious The book has been carefully edited by the competent secretary, Dr H A West of Galveston, Texas

The American Association of Physicians and Surgeons —Transactions for 1893 The ambitious title of this Association would lead us to expect that its transactions would show superior work, and a glance at the volume proves that the expectations are well founded It includes papers by Drs Beverly Robinson, Andrew H Smith, Gilman Thompson, Tyson, Whittaker, Wood, Theobald Smith, Osler, Councilman, Allen Starr and others The articles are illustrated by carefully drawn diagrams and well colored lithographs As the papers have been generally printed elsewhere, either in abstract form or otherwise, special reference to them need not be made here

Vermont State Medical Association —Transactions for 1892 These transactions are included in a compact, neat volume of 175 pages, comprising the address of the president, the papers read at the meeting, and the minutes of the sessions The book is well printed and shows care on part of the members of the publication committee D C Hawley, M D of Burlington is secretary

New Medical College —The Wisconsin College of Physicians and Surgeons was opened in Milwaukee Sept 26, with forty matriculates The Presbyterian Hospital of Milwaukee adjoins the college buildings

DOMESTIC CORRESPONDENCE

The Name is Barker

To the Editor —In your editorial of October 7, entitled "The Place of Ergot in Obstetrics," you speak of a paper on this subject published in your issue of September 23 by Bohn I think there is a mistake on this point, and judge it is my paper you refer to—"The Routine Administration of Ergot after Labor" Please make correction and oblige,

Yours truly,
T Ridgway Barker

MISCELLANY

Meeting of the State Board of Health of Michigan —The following members were present at the meeting of the State Board of Health at the capital, Sept 29-30, 1893 President Wells, Secretary Baker, Drs Granger and Milner, and Prof Fall A very important resolution offered by Dr Baker was unanimously adopted, placing consumption on the list

Navy and medical director of the Cape Fear section He was also for a time the chief medical inspector of the Department of Northern Virginia He was twice promoted for his efficiency and courage on the field of battle This trait of efficiency in the doctor was so notable as to attract attention, and the fact coming to the attention of the Assembly of North Carolina, an Act was passed by them raising his rank from that of colonel to that of brigadier general for "efficient services rendered to sick and wounded"

Notwithstanding the engrossing official and professional duties of Dr Warren during the war, he wrote a work to meet the needs of surgeons in the field, entitled, "Surgery for Field and Hospital" In this publication, which was well received and speedily passed through two editions, the doctor made some valuable original suggestions In 1865, Dr Warren resumed his residence in Baltimore, expecting at the same time to resume his professional duties in the University of Maryland But the changed conditions of the country and the status of the Southern States, the policy of the general government and local interests combined to close the doors of that institution against him

He was not only capable but ambitious and full of energy, and it was mainly at his suggestion and through his efforts that the old Washington University Medical School was revived and rapidly rose to have a commanding position and an able faculty and good patronage In this faculty Dr Warren filled most acceptably the chair of surgery

When the Act of Assembly of Maryland passed requiring an examination and registration of the physicians of the State, Dr Warren was appointed upon the board to carry the law into effect

In 1868 he was elected one of the vice-presidents of the Medical and Chirurgical Faculty of Maryland, and the same year founded the *Medical Bulletin*, which under his management acquired a large circulation

The celebrated Wharton trial, which took place in 1872 brought Dr Warren to the forefront among specialists in criminal trials He was confronted by able physiologists, general practitioners and chemists and their theories and tests shown to be inconclusive The case attracted wide attention not only in America but in Europe Dr Warren ably sustained himself before the court, and his testimony so completely broke down the chemical evidence relied upon by the prosecution as to compel the court to enter a nolle prosequi in the case For some time after the doctor was made a target for critics, not only in the medical profession but by the bar and the public press But it is simple justice to say that no review of his evidence and theory of the case was ever able to demonstrate that he was in error in his views

At the meeting of the American Medical Association in 1872 he was chosen Chairman of the Section of Surgery for the following year He did not, however, attend that meeting or send a report

In 1873 Dr Warren suffered a severe domestic affliction in the death of his devoted wife His health suffered seriously and to change the scene he consented to accept a medical position in the Army of the Khedive of Egypt His service although brief in that country was nevertheless sufficiently conspicuous to place him at the head of the surgical staff It was his good fortune to relieve Kissim Pasha the Minister of War from a strangulated hernia

This operation was undertaken when the war minister's life was despaired of by his own surgeons, and when it was almost impossible for Dr Warren to get any of them to assist him in the operation from a religious dread of being blamed with causing his death But the operation was a success and the result placed the courageous Dr Warren in the front rank of surgeons in the Khedive's army

His splendid success where death was imminent and expected, induced the Khedive to confer upon Dr Warren the Decoration of the Medjidie and the title of Bey

Dr Warren unfortunately contracted a severe form of ophthalmia common in the East and it proving obstinate, he obtained a furlough for six months to visit Paris for treatment Here he was promptly told that one eye was practically lost and that a longer residence in Egypt would result in the loss of the other

He had no alternative but to resign, which he did The Khedive was most kind, and in accepting his resignation spoke of his valuable services in the Egyptian army and wished him long years of usefulness

It was then while still under treatment that he was advised to become a candidate for practice in Paris After many conferences with friends and the earnest advice of Dr Charcot, Breed and other eminent practitioners, he concluded to take up his permanent residence in Paris

Dr Warren's success in the metropolis of France was exceptionally rapid and gratifying Both practice and honors came flowing in upon him From Spain he received the decoration of a "Knight of the order of Isabella the Catholic," for earnest services rendered to Spanish subjects, and from his old Maryland a degree of "Master of Surgery"

Dr Warren both as a boy and through his life proved his indomitable energy and power of work 'He secured a large share of confidence with his professional brethren And yet like all men of force and original ideas, antagonisms were evolved by the friction That he was a man of ability and culture his life and works attest His house in Paris was frequented by Americans and travelers from other countries, and his attentions and hospitalities for years generously bestowed upon numerous friends visiting Paris

MISCELLANY

Meeting of the State Board of Health of Michigan —The following members were present at the meeting of the State Board of Health at the capital, Sept 29-30, 1893 President Wells, Secretary Baker, Drs Granger and Milner, and Prof Fall A very important resolution offered by Dr Baker was unanimously adopted, placing consumption on the list of "dangerous communicable diseases" required by law to be reported by physicians and householders This means that henceforth this "great white plague" which causes far more deaths in Michigan than any other disease, is to be restricted in its ravages This important move by the Board calls for the most earnest cooperation of health officers, physicians and the people generally The resolution is as follows

Resolved, That hereafter, consumption (and other diseases due to the *bacillus tuberculosis*) shall be included in the official list of "diseases dangerous to the public health" referred to in sections 1675 and 1676, Howell's Statutes, requiring notice by householders and physicians to the local health officer, as soon as such a disease is recognized

The reporting of other dangerous diseases to the State Board has enabled it to place pamphlets of instructions just where they would do most good, and at the right time Many years of experience show that restrictive measures recommended by the State Board of Health, relative to dangerous diseases have been the direct means of great reductions in the death rates of dangerous diseases, in some instances the death rate is only about half what it was before the State Board of Health undertook restrictive measures If consumption were reported, it could be dealt with in the same manner and restricted, and many cases of consumption avoided every year It is a disease easily restricted, and the State Board of Health distributes a pamphlet telling just how to do it If the physicians and citizens of Michigan will do with consumption as they have done in the past with other dangerous diseases, and cooperate with the health officers, much suffering and loss of life can be prevented

In connection with the subject of reprinting the leaflet on the restriction of dangerous contagious diseases, in several different languages for distribution to neighbors of persons sick with a dangerous disease, Drs Granger and Milner, the recently appointed members of the Board, had for years watched with interest the good work that these instructive pamphlets had been doing in the restriction and prevention of the several diseases The Board directed the secretary to reprint this leaflet in several different languages Dr Granger said that many of our recently arrived foreigners did not believe that some of these diseases were dangerous, and that this leaflet was just what was wanted to educate this class of people, because diphtheria and other diseases were spread among them and by them to other classes of people

The Board amended its rules for the inspection of immigrants at the Michigan border by adding to Rule 1, "and no immigrant shall come into this State or travel within the State, until inspected under these rules, and until authorized to do so by an inspector appointed or accredited by the Michigan State Board of Health"

Rule 5 was amended so as to hold immigrants until their baggage has been disinfected

An additional rule was adopted as follows

Rule 7—Dangerous communicable diseases being now present in every country from which immigrants are coming into Michigan, no immigrant and no traveler or other person believed by the State Board of Health or by its authorized inspector to have been exposed to and liable to convey cholera, diphtheria or other dangerous communicable disease, shall pass through Michigan, or from one township, city or village to another within the State, without permission from the State Board of Health or its authorized inspector

The following resolution, offered by Dr Granger, was unanimously adopted

Resolved, That it is the will of this Board that the President and Secretary continue to take such action as may be necessary to enforce the rules of this Board and to enforce quarantine at the Michigan border and within the State against diseases dangerous to the public health, and to compel any railroad company operating within the State to obey the State laws and the rules and regulations of the State Board of Health made under the law

Gelsemium in Rheumatism and Neuralgia—In an article with the above title by Dr A Atkinson (*Charlotte Medical Journal*, July, 1893) the author says "Often the trouble in administering the stronger fluid extracts and tinctures lies in the fact that the alcohol will evaporate and the extractive material will gum up and fall to the bottom and the sides of the bottle, and though you may administer a properly assayed article, you will now and then get too much of the active principle and trouble will follow, then, too, people keep medicines too long and they become uncertain and irregular in their action It is safe in administering strong drugs when we can readily procure the alkaloid safely and properly adjusted, to prescribe the article put up by some reliable manufacturer, seeing that it has not been kept too long, and such active drugs are accurately and beautifully put on the market in a soluble form, and even though we have a granule which presents all the appearance of freshness and complete solubility, a good plan is to put it in water a few minutes before administering it or to stick a hole in it and let the patient swallow it in a half softened state There is no question but that the gelsemium will afford relief in many cases of neuralgia, but it must be pushed far enough to secure its physiological effects, just short of injury, if we expect to obtain full relief In facial neuralgia Massini has found that 20 minims every half hour, for three doses almost invariably cures This we would call getting its full effects—1 dram of the tincture in one hour and a half"

Dr Thomas Hoover of the Ohio State Board of Health has proposed a "pure water" plan for the consideration of that body, which is just now giving considerable attention to the question of supplying Ohio cities with healthful water He proposes to have the State take charge of the water supply and furnish all *important* cities and towns by a system of canals fed by Lake Erie

He will not make diplomas for the next three months—Dr. Walter May Rew, whose bogus medical college was exposed last July, was sentenced October 10 to three months imprisonment in the penitentiary

He will be Missed—Dr A K Bond has resigned the editorial chair of the *Maryland Medical Journal*

THE PUBLIC SERVICE

Army Changes Official list of changes in the stations and duties of officers serving in the Medical Department, U S Army, from September 30, 1893 to October 6 1893

Capt William D Crosby Asst Surgeon, is granted leave of absence for three months By direction of the Secretary of War

Majors Alfred A Woodhull and Alfred C Girard Surgeons, are detailed as delegates to represent the Medical Department of the Army at the annual meeting of the American Public Health Association, to be held in Chicago, Ill, from the 9th to the 14th of October, 1893

ADDRESS

SANITARY ADMINISTRATION

Read in the Section on State Medicine, at the Forty fourth Annual Meeting of the American Medical Association

BY C A LINDSLEY, M D
CHAIRMAN OF SECTION ON STATE MEDICINE

The value of health to the family, to the community and to the nation has come to be understood and appreciated as it never was before During the last few decades public sanitation has made surprising progress The positive discoveries relating to the protection and preservation of health have proved their verity by their practical application, and have strengthened the claim of public hygiene to be ranked among the applied sciences In scarcely any department of human progress have the indications of successful accomplishment been more marked, more satisfactory, or of greater direct value to the welfare and happiness of mankind, than in the unfolding and development of the principles and natural laws upon which modern scientific public hygiene is based

Let us take a retrospective glance at the beginning of a movement which is still progressing with an undiminished impetus In the East End of London, known as Whitechapel, recently made notorious by several brutal murders, at a place situated on the borders of a large and stagnant pond there occurred in 1838 a severe outbreak of disease The abruptness, the violence and the limits of the epidemic clearly indicated some local cause The late Edwin Chadwick, who had already made an enviable reputation as an original thinker and as a man of rare judgment and great executive ability, was applied to by the parochial authorities for advice He was at the time the Secretary of the Poor Law Board He readily persuaded his Board to institute a medical commission, and himself selected its members He directed the character and extent of the investigation He did not limit it to the existing epidemic, but made it to include the sanitary condition of the whole city of London The judgment and foresight of Edwin Chadwick were never more conspicuously exhibited than in all this proceeding 1, in the selection of the commission, who were among the most competent of living men, 2, in seizing the occasion as an object lesson to impress the public mind with the importance of public hygiene

The gravity of the outbreak justified the procedure and the man and the opportunity came together [1]No commission of this character had ever before been formed The exhaustive and instructive reports which were made, detailing with eloquent accuracy and fearless plainness of speech the shameless pollution of the water supply, and other dangerous influences to which the people in the chief city of the world were exposed, greatly aroused public attention "These reports," says B W Richardson, "became texts in sanitation, and were so much in demand that many thousands were distributed among the people" It was the beginning of public interest in sanitary reform It made an impression that could not be readily effaced It was not only instructive, but it was also very suggestive And the suggestions presently became active realities Thus, if diseases result from unwholesome surroundings, with what diseases are such conditions most associated?

The next step came naturally, but only as such great movements do, after much effort and by powerful influence, but it came, to-wit the registration of the causes of death This result to-wit the enactment of the registration law of the causes of death, can be directly traced to the influence of the reports on the outbreaks of the epidemic in the East End of London in 1838 It gave to the world its most splendid statistician, Dr William Farr, who for more than forty years was the genius who directed and utilized the registration of the vital statistics of England

In these two points we have the foundation of practical public hygiene, two cardinal principles, viz sanitary inspection and the registration of the causes of death It is not necessary in this presence to trace the progress of public sanitation from that time to the present We all know something of the rapid growth in practical methods, and of the marvelous results which they have accomplished

The prominent idea which it is my aim to develop to day is, that in this country, that is, in our own United States, the practice of public hygiene lags far behind the theory and the science of it In the old and long established governments of Europe, the advantages derived from science take effect earlier than they do in this country The people there are more accustomed to trust and obey the powers that be than they are here Here, if the people have not the gratification of trying to turn out all the incumbents of public offices every year they feel that they are not enjoying all the privileges of a free country Then again, the doctrine of self-government among us is carried to an extreme degree in practice, so that the principle of the greatest good to the greatest number is often sacrificed to the claim that every community, however small, has the right to govern itself in all matters pertaining to local interests, and the health of a community is still too often regarded as preeminently a matter of only local interest

Hence in some States, especially in my own, the sanitary administration is divided into just as many little sovereignties as there are local governments of any kind Every town, every borough and every city in Connecticut has its own health authorities, each having jurisdiction over their own little territory, and each making sanitary regulations and exercising their powers entirely independently and without any reference to adjoining similar dynasties. They are under no common direction and have no uniform system of practice. This might not be so unfortunate in its results if unsanitary influences and contagions were accustomed to show any respect for town authorities or city limitations. Now it is quite obvious, on a little reflection, that very serious consequences will naturally result from these queer conditions. One exceedingly unfavorable effect is this: it rarely happens that the limited jurisdiction of a health officer affords him occupation enough to give him a reasonable support. He, therefore, in the great majority of instances regards his official duties as secondary in importance and, consequently, they are usually performed only in a perfunctory manner, or not at all, and often these offices are only accepted by men of inferior ability.

---

[1] The Health of Nations vol 1 p xliii

Again, the uncertain tenure of office, from the frequent popular elections for the usual term of only one year, tends to prevent the incumbent from acquiring any enthusiasm or interest in his work. Still again, the public mind either assumes that no special skill or fitness for the office is necessary, or else that the possession of such skill and fitness is universal, and as the office is not usually remunerative, it is not apt to be accepted by competent citizens or else it is made an appendage, ex officio to some other office, the functions of which may not have the most remote relationship to the proper qualifications and duties of the sanitary officer. This clearly indicates a want of proper appreciation on the part of the public of the true functions of such an officer and of their importance.

Sanitary administration, whether in a rural or an urban community, deals with the highest interests of man in the social state, it aims to provide a safeguard to every individual, and protect him from the perils inherent to life in communities, it is one of the chief factors in the promotion of public prosperity and general happiness. For there is nothing so disastrous to the public welfare, nothing so productive of personal misery and suffering, as disease and death. A nation physically feeble, and whose people are subject to frequent epidemics can not be prosperous, it can not be happy. When, therefore, we reflect upon these facts, the apathy and indifference of the public to this subject is cause for profound surprise. "For life is not to live, but to be well," said Martial, an epigrammatic poet of the first century.

The principles of self-government which these little towns feel that it is an injustice to be deprived of, are not rightly comprehended by the popular mind. If government is needed at all, it is highly desirable that those who are governed shall get all the advantages possible from the restrictions imposed upon them. Hence when different communities in neighboring towns and cities have a common interest in the results of government, it would seemingly go without saying, that there should be some common adjustment and unification of the code of laws in which they are all mutually concerned. It has long been recognized by wise legislators, "that every branch of administration needs a central direction, which holds in its hands all the threads of the different local portions." Isolated, separate, independent self-governments, by towns and municipalities, have no cohesiveness or uniformity of methods. They lack the advantage of guidance by a central authority, which with a comprehensive acquaintance with their common, as well as their individual needs, can weld together and wisely direct and control their sanitary work.

The practical sanitation of to day has outgrown the lethal methods which have been so long in vogue. The pressing needs of the times in regard to the conservation of public health, are that such radical changes shall be made, in old ways of sanitary administration, as will enable the most economical and efficient application of the laws of sanitary science. Sanitary administration is sometimes designated "State medicine," by which may be understood that function of the State, in the exercise of which it aims to put the people of the State in such relation with themselves and their environment, in all things affecting their health, that they will need to take the minimum amount of medicine. This implies a general and comprehensive system for the State, with a central authoritative supervision and control of subordinate officials. A central administration, in which the same thing will be always done in much the same way in any part of the State where it is needed to be done at all, would be a vastly different thing from the too prevalent practice in many places of what might be called "town medicine," in contrast with "State medicine." Town medicine, in which each town is an independent, isolated and disjointed government whose appreciation of the principles of public hygiene are as narrow as the limit of its own little territory, and whose policy is "Not to act until obliged to do so, and then to do as little as possible."

The inefficiency, the waste of energy, the want of applied intelligence, or worse, energy misapplied through ignorance, all condemn town medicine as inadequate, expensive and largely barren of results. Public hygiene deals not alone with local conditions. It has to do with the welfare of populations settled over wide areas of territory, and under such varying conditions that the common good of the whole can not be attained without a comprehensive acquaintance of the mutual relations and interests which the separate towns or communities within those areas may bear each other. Town medicine as such is obsolete, belongs to a by-gone age and should no longer assume a responsibility for which in the nature of things it is incompetent.

The true function of town sanitary administration in the future is in the capacity of a component part of a general comprehensive system, guided and directed in its general work by a central authority, upon plans and methods devised with reference to the best good of all the communities interested. In this way, not only will the particular town be benefited, but it will derive a great reflex benefit from the better sanitary condition of all surrounding towns. Sanitary science is of recent growth, but its growth has been vigorous and healthy. Treatises on public hygiene have been written since the days of Hippocrates, but it is only within the last two decades that accumulating knowledge has crystallized in form and taken a scientific character. In the words of Dr. Guy: "It has to do with persons of every rank, of both sexes, of every age. It takes cognizance of the houses and places in which they live; of their occupations and modes of life; of the food they eat, the water they drink, the air they breathe. It follows the child to school, the laborer and artisan into the field, the mine, the factory, the workshop, the sick man into the hospital, the pauper into the workhouse, the lunatic to the asylum, the thief to the prison. It is with the sailor in his ship, the soldier in his barrack, and it accompanies the emigrant to his new home beyond the seas. To all these, it makes application of a knowledge remarkable for its amount, and the great variety of sources whence it is derived. To physiology and medicine it is indebted for what it knows of health and disease, it levies large contributions on chemistry, geology and meteorology, it cooperates with the architect and engineer, its work commends itself to the moralist and divine."

Sanitation has advanced beyond the mere suppression of those grosser nuisances which conspicuously offend the senses, and are so often the subjects of complaints between neighbors. The deadly maladies like typhoid fever, cholera, consumption, etc., do not announce their presence to their victim by appreciable signals, until they have passed the guards and have gained possession of the citadel. They do not herald their approach by any impression on the sense of sight or smell, of taste or touch, but they silently enter, intrench themselves in our vitals, and begin their fatal work before we are conscious of their presence. But modern sanitation has put detectives on their track who have traced them to their lurking places, have studied their career and written their biographies. We know now, somewhat, where to find these secret foes, through what avenues they make their attack, and can in corresponding measure defend ourselves. But the system of defense involves a wider field of operations than the limits of a town or city, and a higher standard of official ability and special training than can reasonably be expected to be possessed by the average town selectman or village justice.

The exponent of practical hygiene in the future must be not only a physician and microscopist, but also a chemist, bacteriologist and geologist. All these sciences come into active demand in the exercise of the functions of a sound and efficient sanitary administration. It is quite obvious, from the rarity and character of these requirements, that they can not be economically employed separately and independently by small communities, living within limited areas of territory. Such communities would not often possess the men competent for such service, and would be unable to afford the remuneration which so high a standard of qualifications could justly demand. Moreover the principles of modern sanitary administration are of universal application, and therefore every consideration of expediency, as well as of economy, would lead to the utilization of acquired knowledge and trained skill by as large a constituency as is practicable.

It rarely happens that the health and well being of a town or even a community are *dependent upon* conditions which are wholly self-contained. In the great majority of instances, the sanitary state of a town or city is very largely at the mercy of things beyond its own boundaries. Those two great factors in public health, the sources of water supply and the means of sewage disposal, are seldom found wholly within the limits of any town and one or both, nine times in ten, must be sought for on territory not its own, but beyond the bounds of its jurisdiction. Nor only that, but the hygienic questions of most importance to the best success of these undertakings, require for their solution a larger experience and a wider range of knowledge than can ordinarily be found in a local health board. Besides these questions are to a considerable degree constantly recurring, not merely with reference to new enterprises, but in the care and proper maintenance of plants already established and in working order. Something above the average standard of attainments by local boards of health is requisite for the best management of most public undertakings of this kind, in which the general interests of all the towns and cities in a State are more or less concerned. When the general interest is so intimately connected, it follows without argument that whatever is best for the general welfare should so far as practicable be adopted. At least it is reasonable, that any one locality or community should be restrained by some authority from doing that which, selfishly designed solely for its own benefit, may be very disastrous to the welfare of other communities, or on the other hand be required not to neglect doing something essential to the welfare of itself and of other communities. It is without question the true policy of a State to provide for the best good of all its citizens, and most of the States in the Union have recognized that policy as regards health, by establishing State Boards of Health.

These State Boards are, indeed, charged with the duties of investigating the causes of disease, and especially of epidemics, the various effects upon health of localities, occupations, etc. They are required to advise regarding water supplies, systems of sewerage, the means of arresting the spread of contagious diseases and kindred subjects. This is very wise and judicious, but in some of the States, more particularly in the East, the best results are wanting, from the fact that after the State has provided the means of knowing what is the best thing to do in any given case, it has not provided any way of preventing communities from doing *the worst thing* instead of the best if they choose to. While the State thus admits the necessity of supplying to its citizens a sound and scientific standard of public hygiene through its State Board, it omits to insure the advantages which should follow, by neglecting to confer upon said State Board any authority by which local health officers may be held responsible for their observance of such standard. It is quite parallel to conducting a campaign against an invading foe, by directing the commander in chief of the army to instruct the colonels and captains upon the best plan of defense, and when and how they should dispose their respective commands, and then leaving it to the individual option of those officers whether they will be guided or not by such instruction.

Another forcible illustration of the need of making local health boards responsible for their official work, may be found in the management of local epidemics of contagious diseases. It is well known that by isolation and disinfection contagious diseases can be restricted. But the unsystematic, haphazard, half way efforts to accomplish these objects by the average town board of health seldom do any good, and the contagion goes whither it will, until the susceptible material in the community is exhausted and then the epidemic ceases spontaneously. While these constant failures to restrict disease by the appointed officials may bring isolation and disinfection into public contempt, still isolation and disinfection remain the best and most effective means we know It is not the means which should be in contempt, but the incompetent officials who know not how to use them Where, in your experience, is the practice of disinfection satisfactorily performed by town boards of health? The absurdity of telling the family of the sick persons to burn some sulphur in the house, after recovery or death (a very common thing to do) is but a silly caricature of real disinfection

Public establishments for disinfection should exist in every community, and should always be in the charge of competent and intelligent men Yet I will boldly venture the assertion that Connecticut is not the only State in the Union which is wholly unprovided with this most necessary and essential means of public safety The only reason why disinfection stations are not established is the cost, but they are not so costly as epidemics

Now, in conclusion, let me briefly outline the principle of sanitary administration which I have attempted to defend the limit of this address will not admit of detail Public sanitation is no longer the simple matter of half a century ago It has become an elaborate system involving in its practice an acquaintance with many branches of science It has outgrown the comprehension of the town supervision, the town committee man or the town selectman But the town by common consent is still the unit in sanitary administration, and the town health officer must still remain an essential factor in the system, only he must possess some qualifications for the office and can no longer be independent The close relationship of towns, the intimate intercourse of their peoples by reason of modern facilities for rapid transit, produces in every town a direct interest in other towns, and other towns in like manner have an interest in it

In a matter so important as the public health, this common interest demands that towns shall not continue to be irresponsible separate entities, doing or not doing at their option concerning affairs in which other towns are also deeply concerned The town health officer shall have the necessary authority It is not designed to abolish local self-government in sanitary matters, but to strengthen it and combine responsibility with it Just as an individual may abate a nuisance on his own premises in his own way, but is liable for penalties if his way is not effectual, so local health officers should be responsible to a higher authority if they fail of their duty in the administration of sanitary laws in their own jurisdiction I think the idea may be expressed in one sentence in local matters concerning sanitation, let there be central supervision with authority, and local administration with responsibility

GIFT TO THE CAMDEN MEDICAL SOCIETY —At a meeting of the Camden City Medical Society, Colonel J R Johnson presented to the Society a large oil painting of the "First Dissection" Dr J M Ridge made the presentation speech, and the painting was received on behalf of the Society by Dr O B Gross A rising vote of thanks was extended to the artist, after which a collation was served —*Philadelphia Public Ledger*

A CASE OF SYMPATHETIC NEURITIS AFTER EVISCERATION OF THE EYEBALL

Read before the Section on Ophthalmology at the Forty fourth Annual Meeting of the American Medical Association

BY F C HOTZ, M D

PROFESSOR OF OPHTHALMOLOGY IN THE CHICAGO POLICLINIC

Evisceration of the eyeball was introduced by Prof Graefe in Germany and Dr Mules in England ten years ago as a substitute for enucleation, for the reason that it was a less dangerous operation and furnished better conditions for the artificial eye The first report[1] on a larger number of eviscerations performed by Graefe seemed to sustain the favorable opinion of the originators, for among 240 eviscerations there was neither a death nor an instance of sympathetic inflammation after the operation

But soon matters began to take a different aspect. Prof Schuleck of Budapest, for instance, lost two patients among thirty-six eviscerations in the first week after the operation[2] and Dr Cross reported two cases of sympathetic ophthalmitis occurring after evisceration[3] But as Dr Cross had inserted a so-called artificial vitreous, it was maintained the sympathetic inflammation in these cases could not be charged to the operation, but was induced by the foreign bodies

As no other instances seem to have been reported, I wish to present to the Section the following case in which the effects of the evisceration have not been modified or prejudiced by the introduction of an artificial vitreous, but in which two weeks after the operation an optic neuritis appeared in the other eye under circumstances which seem to warrant the opinion that we had to deal with a sympathetic affection.

Aug 6, 1891, Frank S , 21 years old, bookkeeper consulted me in regard to his eyes When but two years old, he accidentally wounded his right eye with a pen-knife, the blade piercing the lower sclero corneal border and passing through iris and ciliary ring into the vitreous A very mild form of irido-cyclitis followed this injury , in two weeks the eye had apparently recovered and its external appearance was as perfect as that of its fellow , but the sight was gone The boy grew up and went through the public school and the high school , and not for one single minute during his entire school life did this blind eye give him any trouble, though it had gradually become perceptibly smaller

In the summer of 1888, it became troublesome for the first time, getting red and tender to the touch and making the other eye rather sensitive to the light, so much so that on some days it was almost impossible for him to do his bookkeeping although his sight always remained clear and strong With the advent of cooler weather all these symptoms disappeared and during the next winter and spring he experienced no trouble, and could work over his books in daytime and read at night with perfect ease But in the summer of 1889 the eye again became red and troublesome, and again the irritation subsided as soon as the weather grew cooler The same thing happened in summer of 1890 , and when the patient came to see me in August 1891, the same trouble had been annoying him for two weeks past

I found the right eye very small, red and quite sensitive to slight pressure , the left eye showed normal vision, refraction, and fundus , but it was a little sensitive to light and became quite red and watery after reading a few minutes. I told the patient in my opinion the proper thing to do in his case was to remove the offending atrophied eye My advice was readily accepted , the patient went to the hospital where I eviscerated[4] the eye August 10 Chloroform was administered, the face had been thoroughly scrubbed with soap and water, the eyelids, eyeball and conjunctiva were washed with sublimate solution 1 to 5000, all the instruments were first immersed in 95 per cent carbolic acid, then treated with boiling water and kept in sterilized water till the end of the operation The eyeball was opened by a circular incision just behind the sclero corneal border, the retina was found completely detached and "chorded," and the choroid was easily separated from the inner surface of the sclera by a flattened scoop The posterior portion of the choroid was calcareous When every trace of the contents was removed, the inner surface of the sclera was washed with carbolic acid and dusted over with iodoform, and the conjunctiva drawn over the scleral wound and brought together by a purse-string suture The eye was once more washed out with the sublimate solution and dressed with borated cotton and sterilized bandage

[1] Dr Bunge Ueber Exenteration des Anges 1887

[2] Otto Becker enucleation and exenteration, 1888

[3] British Medical Journal July 1887

[4] I decided on evisceration for cosmetic reasons This operation is said to yield a larger stump than enucleation and inasmuch as the growth of the right orbit had been retarded and would allow the insertion of a small artificial eye only I thought the larger stump might give the small glass eye a fuller appearance by preventing its sinking back into the orbit and therefore be of some real cosmetic value to my patient

August 11 —Violent headache, great lid swelling and much chemosis of conjunctiva, bloody serum has been and still is oozing from the stump

August 13 —Patient still in bed, the pain in the head is decreasing no more oozing from stump since yesterday

August 20 —No more headache since two days, only a dull pain over right eye, swelling of upper lid gone, but still considerable chemosis of conjunctiva, stump large and firm Patient is allowed to go home but is advised to abstain yet from reading The left eye has been free from the photophobia since the operation and appears well in every respect

August 29 —Patient calls at the office, the dull pain over the right eye has continued all the time, the conjunctiva is still swollen and pressure on the stump causes deep seated pain in the orbit Since two days the patient has noticed the left eye was getting sensitive to light again, and on pressing on the eyeball he felt a dull pain back of the eye, and since this morning he observed a peculiar unsteadiness of vision, he sees everything very distinctly at first but only for a moment, for instance, when looking at the test types he can read No xx, but the letters gradually seem to fade away and then come back No redness, pupil active, vision clear, but papilla seems redder than at previous examinations

September 1 —Unsteadiness of sight more annoying, V = 20 20, papilla decidedly hyperemic Pain and tenderness of stump still present Hot water compresses ordered on stump, and calomel internally, gr ¼, three times daily

September 4 —V 20 30 only, papilla very red, and its nasal border veiled by a gray mist which extends a short distance over the adjacent retina

September 9 —V = 20-40, papilla still more *indistinct* Pain and tenderness of the stump of right eye has been much less these two days

From this day on the eye began to improve and by October 1, it had regained normal and steady vision (20-20), the papilla showed normal color and well defined border

December 1 —Patient called to see about wearing an artificial eye, the stump of the right eye was so shrunken by that time that it showed no essential difference from the stump after enucleation He had been at his work the past four weeks and experienced no trouble with his eye And on inquiry I learned that during last summer and autumn he had no return of his eye trouble

Remarks —The history of this case, I think, leaves no room for doubting the sympathetic nature of the disturbance of the left eye, and I also think the clinical evidence is sufficiently clear to point out the important and significant difference in the character of the sympathetic disturbance before and after the evisceration We have seen that for several years the left eye had been troubled by periodical attacks of photophobia accommodative asthenopia and irritability unquestionably induced by the tender state of the atrophic right eye But for all these several attacks and though the last attack immediately preceding the operation had lasted two whole weeks we have found the vision still unimpaired and the fundus in a normal condition, and therefore come to the conclusion that these attacks preceding the evisceration were due to *sympathetic irritation* which was promptly relieved by removing the exciting cause in the right eye (its degenerated contents) The right eye remained perfectly quiet after the evisceration for the next seventeen days when it again became sensitive to light and reading, but this time the vision soon became impaired and the ophthalmoscope disclosed the signs of a rapidly progressive optic neuritis This neuritis had certainly no connection with the sympathetic irritation which preceded the evisceration, for we know sympathetic irritation never leads to sympathetic inflammation But when we consider what occurred in and about the right eye during these seventeen days after the evisceration, I think, we may find the cause of the neuritis of the left eye The operation was followed by great swelling of the lids and conjunctiva and by severe pain extending from the right eye over the whole right side of the head, after ten days this violent headache subsided into a dull continuous pain over the right eye which with the chemosis of the conjunctiva lasted nearly two weeks longer

In these symptoms we have the evidence of an acute inflammation which proceeded from the eviscerated eye This inflammation probably followed the tract of the optic nerve to the chiasma, there invaded the optic nerve of the left eye and following its tract down to the eyeball finally produced the ophthalmoscopic evidence of neuritis in the papilla of the left eye In this way I think the optic neuritis in our case was developed and, therefore, may justly be looked upon as the after effect of the evisceration This opinion is materially strengthened by the fact that the neuritis in the left eye did not begin to subside until all signs of inflammation in the right eye had disappeared And when we consider the fact that a violent and prolonged irritation after evisceration such as we have observed in this case, is not an unusual occurrence, when we know it occurs after smooth and easy operations as well as when the evisceration has been difficult and tedious, it must be admitted that even the most carefully executed evisceration creates conditions which may possibly lead to sympathetic inflammation, and that in this respect evisceration appears a less safe operation than enucleation

In the after effects evisceration compares very unfavorably with enucleation After the latter operation the patient seldom suffers much, and may be discharged from the hospital in three to four days After evisceration great pain is the rule, as we have seen, and the recovery is very slow, Dr Bunge found in 240 cases nine days, Dr Hecht in Schweigger's Klinik found in thirty-seven cases ten and two-fifth days the average time which the patient had to remain in the hospital

It is claimed in favor of evisceration[*] that it leaves a larger, more movable stump and thus furnishes better conditions for the movements of the artificial eye This alleged cosmetic advantage seems to be generally conceded, and yet on closer examination it turns out to be all a myth In order to obtain some accurate information in regard to the apparent movements of the artificial eye I measured its outward and inward rotations by the perimeter in the same way as we determine the degree of convergence or divergence in strabismus I told the patient to look as far as he could to the right and found out at which angle of the perimeter the candle light was reflected in the center of the cornea of the glass eye, and then I made him turn his eyes as far to the left as he could and again measured by the light reflex on its cornea the position of the glass eye As the artificial eye follows as well as it can the rotations of the natural eye, I believe these measurements thus obtained represent the extreme limits of motion the artificial eye was capable of in every case The results of my tests are given in the following instructive table

---

[*] Dr Bunge, Exenteration, p 64

PERIMETRIC MEASUREMENTS OF THE LATERAL MOVEMENTS OF ARTIFICIAL EYES

PATIENT S	AGE	STUMP	WHEN OPERATION WAS PERFORMED	DEGREES OF ROTATION	
				INWARD	OUTWARD
L S	45	Enucleation	10 years ago	15	25
F S,	21	Evisceration	3 months ago	20	20
A C	21	Enucleation	1 year ago	15	15
Mrs M,	36	Evisceration	4 months ago	15	25
Mrs E	50	Enucleation	5½ months ago	20	25
G L,	24	Enucleation	1 month ago	20	20
M J,	42	Atrophic Eye	20 years ago	10	15
L H	22	Enucleation	6 weeks ago	15	20
Mrs L	20	Atrophic Eye	10 years ago	15	30

These measurements show there is absolutely no difference in the extent of the lateral movements of the glass eye, worn on an evisceration stump, and that worn on an enucleation stump, in either case the inward movements (adduction) varied between 15 and 20 degrees and the outward movements (abduction) between 15 and 25 degrees These results were not surprising to me, for though I have heard so much about the larger, better stumps gained by evisceration I have found these stumps shrink away so much that three months after the operations there is no more of them left than what we find after a suppuration of the globe, and that it is difficult to tell by the stump whether enucleation or evisceration has been performed This observation I have made not only in my own cases but also in eyes which had been eviscerated by other surgeons

But even granting a larger permanent stump to the evisceration, I still maintain the artificial eye does not gain any material advantage by it The largest and best movable stumps, superior to any furnished by evisceration, undoubtedly are those slightly atrophic eyeballs with well preserved vitreous, but complete loss of the cornea and iris (as the result of sloughing or surgical operation) Glass eyes can be worn over such atrophic globes, but they do not show any superior mobility In my table there are two such cases, and we see that the one shows an unusually limited movement, and the other (the last in the list) shows no better adduction (15 degrees) than we get by enucleation or evisceration cases and exceeds their best abduction by 5 degrees only These atrophic eyeballs had an excellent range of lateral rotation, and if the artificial eye could be cemented onto the atropic globe it would, of course, follow the rotations of the latter, and the cosmetic effect would be perfect, because the artificial cornea would describe lateral rotations as perfectly as the natural cornea But as the artificial eye is not fastened to the stump, the latter does not impart its motions to the super-imposed glass shell and the axis of rotation of the glass eye lies much in front of the stump When, therefore, the glass eye seems to turn to the right or left, its cornea shows very little real lateral movement, its principal motion being a rotation on its vertical axis so that its center faces to the right or left On this account the movements of an artificial eye will always be confined to narrow limits whether the glass shell be inserted after enucleation or evisceration*

If I sum up all the clinical facts, I should say evisceration has nothing to show in its favor, while it compares decidedly unfavorably with enucleation in the frequent violent reaction and slow recovery, and therefore does not deserve to take the place of enucleation

---

PANOPHTHALMITIS—FATAL MENINGITIS FOLLOWING ENUCLEATION OF THE EYE

Read in the Section on Ophthalmology at the Forty fourth Annual Meeting of the American Medical Association

BY S D RISLEY, M D

ATTENDING SURGEON AT THE WILLS EYE HOSPITAL LECTURER ON OPHTHALMOLOGY IN THE UNIVERSITY OF PENNSYLVANIA PROFESSOR OF OPHTHALMOLOGY IN THE PHILADELPHIA POLICLINIC AND COLLEGE FOR GRADUATES IN MEDICINE, PHILADELPHIA

John M , age 47, but appearing at least 67, presented himself at the Wills Eye Hospital Dec 12, 1892, bearing a letter from his physician Dr D T Lainé of Media, Penn , under whose care he has been for a severe attack of iritis in the left eye The disease proving rebellious, he was advised to seek hospital treatment He was in feeble health, suffering from severe pain in the eyeball and with violent left hemicrania, vision was reduced to quantitative perception of light There was deep ciliary injection, small pupil, slight haze of the cornea and the remnant of a blood clot was still lying in the lower angle of the anterior chamber There were numerous posterior synechia and dilated blood vessels could be seen coursing over the surface of the iris Tension was normal but the anterior chamber shallow He was placed in bed, blood extracted from the left temple and calomel and soda purge given, eserin being instilled locally He experienced very prompt relief and one week later vision was somewhat improved, the blood clot absorbed, and the ciliary injection less marked but no view of the fundus could be obtained There was simply a gray-red reflex from the pupil When seen two days later, there was a fresh red blood clot lying in the pupil and on the upper and inner pupillary rim of the iris and a large blood vessel could be seen entering it from which the blood was apparently issuing As yet there was no pain but the hemorrhage was soon followed by decided increase of tension and the ball became tender to pressure and with it his headache returned He lost appetite, became sleepless and the general health rapidly declined Under a careful regimen, however, the health improved, the blood clot once more absorbed and the eye became quiet but showed a tendency to frequent recurrences of increased tension and ciliary redness During one of the intervals of freedom from acute symptoms a broad iridectomy was made upward The iris was found friable, the operation was smooth and successful, but bleeding was profuse and the eye was bandaged with the anterior chamber filled with blood There was no undue reaction and the blood clot slowly absorbed, but the wound refused to heal In ten days there was a pouting black mass lying in the wound, but slightly elevated above the corneal limbus, and occupying the entire line of incision The operation was done under antiseptic precaution and the eye was subsequently kept bandaged, being thoroughly washed with bichlorid solution at each dressing and dusted with iodoform There were no visible signs of suppuration but his health steadily failed, his hands were hot and there was a hectic flush on his cheeks, but only slight if any rise in his temperature The eyeball was soft, there was no dread of light and no pain or headache He was greatly depressed in spirts felt that he was going to die and begged to be allowed to return to his home The eye was then enucleated on Jan 25 1893, and found filled with pus The nerve was severed well back, the orbit thoroughly drenched with bichlorid of mercury solution, well dusted with iodoform and bandaged for twelve hours He made a rapid and favorable recovery without suppuration of the stump The infiltration of the tissues of the orbit absorbed rather more slowly than usual but his health rapidly improved so that on the fourteenth day February 7, he was discharged from the hospital apparently well, certainly with no symptoms to awaken apprehension regarding his future One week later February 15, twenty one days after the excision of the eyeball, he sent for his physician, Dr Lainé, but in his absence was seen by Dr J H Fronfield, to whom I am indebted for the following history He complained only of weakness and disgust for food, the temperature was normal and throughout the subsequent history, remained either normal or sub-normal, although taken twice daily at no time was there any rise There was at this time some suppuration of the stump, he was anemic, the tongue pale, large, flabby and indented He was not considered seriously ill Calomel and soda were prescribed to move the bowels and he received an elixir of iron, quinin and strychnia as a tonic

February 18, 10 A M Bowels have been freely moved but can not take the tonic Urine free from albumen 7 P M Decidedly weaker, very melancholy, is sure he will die No pain in the eye, pupil reacts promptly

February 19 In bed, very drowsy, is aroused with much difficulty, rapid pulse, reflexes are normal The right eye shows no muscular deviation, there is no ptosis or dread of light There is no increased suppuration of the stump and no swelling of the orbital tissues, respiration very irregular, at times normal and then extremely rapid subsiding once more to normal No tenderness of the spine, hearing good, no pain and no vomiting *Obstinate constipation*

February 20 Only partially aroused and that with great difficulty and lapses immediately into unconsciousness The head is drawn backward From this time he remained in a state of profound coma with irregular breathing and the backward traction of the head developed into marked tonic opisthotonos, the man resting upon his heels and head until the 26th when he died

No autopsy could be secured At my request Drs G C Ellet and W R Parker, resident surgeons at the Wills Eye Hospital, made for me a careful examination of the excised ball, and I append their report "In the region of the corneal wound the epithelium has proliferated considerably and the superficial layers of the cornea are thickly infiltrated with round cells There is no union of the lips of the wound, the space between them being occupied by iris tissue covered with organizing inflammatory products The iris is pushed forward, adherent to the cornea by heavy organizing bands in the neighborhood of the wound, the anterior chamber being reduced to a slit The portion of the iris which is not prolapsed is covered with a layer of lymph and pus, and where the pupillary space is visible it is filled with a heavy membrane continuous with that in the iris This is continued backward on the under surface of the iris, filling the posterior chamber, and passing with a mass of pus which fills the vitreous chamber The ciliary body seems but little affected, but the retina and choroid are thickly infiltrated with pus as far anteriorly as they can be identified The inner layers of the sclerotic are also attacked Further back, the retina is lost from the specimen Toward the posterior part of the eye the choroid is represented by a thick layer of pus thrown into folds, and stellate pigment cells scattered through it serving to identify it as choroid, none of the vascular structures being visible The optic nerve is in a state of inflammation, the round celled infiltration being pronounced as far back as the specimen shows A few lymph corpuscles are present in the nerve There are no changes in its vessels "

Dr Fronfield's careful report leaves no room for question but that this man's fatal illness was due to cerebro-spinal meningitis The consideration of great interest to the ophthalmic surgeon is its possible relation to his suppurative panophthalmitis and the enucleation of the eyeball The exact character of the intracranial lesion must, in the absence of an autopsy, remain in doubt

Two possible explanations are at hand first, that the meningitis was a mere coincidence, having no relation to the ocular conditions, the other, that the fatal meningitis was infectious and that it was set up by germs conveyed through the cut tissues and open vessels in the orbit to the membranes and venous sinuses of the brain It would be a comforting view of the case could we feel assured that the first proposition was a correct solution of the unfortunate sequel

The very close relation that exists between the eyeball and the intracranial mass would lead us to anticipate serious danger to life from its excision Such expectation would moreover be greatly strengthened by the frequency with which we observe ocular disease as secondary to disease of the brain and its membranes But however frequently we may witness ocular disturbances as secondary to intracranial inflammations, experience shows that the reverse is extremely rare, except in the case of malignant disease Furthermore it has been shown by ample experience that excision of the eyeball is fraught with but little danger to the patient That it is not entirely devoid of danger to life, however, is evidenced in the fact that there have been forty-six reported cases of meningitis, forty-two of which proved fatal Four of these, all fatal, should possibly be excluded as having been subject to malignant disease

These cases have been again and again tabulated and reviewed, so that it is not necessary for me to go over this well-known field again, except to add to the number already known Individual cases were collected by Nettleship to the number of thirty-four in 1886, (Transactions Ophthalmological Society United Kingdom 1886) including a case occurring in his own hands at the Moorfields Hospital, and which he made the basis of an admirable review of the subject In the discussion which followed, McHardy reported two cases of fatal meningitis following the removal of the eyeball, and a third where the meningitis and death followed suppurative panophthalmitis, the ball having been freely opened but not removed Dr Joseph A Andrews, in the *New York Medical Journal*, Dec 29, 1888, has again tabulated the cases, omitting the four non-fatal cases of Nettleship and adding others finding thirty six fatal cases My own case here reported, Mr McHardy's two cases and three others occurring in the practice of my colleagues in Philadelphia but not heretofore reported make a total of forty-six cases of meningitis following enucleation

H D Noyes, M D, has again briefly reviewed the subject in the Transactions American Ophthalmological Society for 1888–89, with the intention of studying the dangers attending excision in suppurative panophthalmitis He there collects 3,742 enucleations at the various clinics with but one death, and suggests that the deaths which have occurred are probably about one for 4,000 enucleations There have, however, been 1,131 enucleations at the Wills Hospital in Philadelphia in twenty years, eighty-five of which are recorded as for suppurative panophthalmitis, and one death here reported Three of my colleagues report each one case of fatal meningitis as having occurred in their practice there during the years mentioned, but no details of them could be found on the hospital records by the House Surgeon, Dr Parker who kindly went over the books for me. This would make a total of 4,873 enucleations and five deaths if these three cases and my own are included On the other hand, there has been no case of meningitis at the large clinical service at the

University Hospital since it was established In any case it is plain from these figures that the operation for excision of the eyeball is more free from danger than one would expect, having in view its critical anatomical relations

The fear which is entertained regarding the danger from the excision of suppurating balls, moreover, does not seem to find support by reviewing the testimony furnished by the reported cases, since only half of the cases, where the point is mentioned were suppurating eyes This statement, it is true, loses some of its force by the fact that the teaching of von Graefe as to the danger to be apprehended from excising suppurating eyes has doubtless had a restraining influence over the practice of surgeons in such cases The fact that the excised eye had been opened, either by accident, operation or inflammation, as pointed out by Nettleship, seems to be of more significance than the presence of visible pus, for in a large majority of all the cases where the history is sufficiently complete to determine the point, the eyes had at some time been opened

In the study of my own case here reported, in the light of the published experiences one finds much confusing testimony In the first place the length of time which intervened between the excision and the onset of the meningitis favors the view which would regard the meningitis as a coincidence The longest time heretofore reported is eight days while in mine it was twenty-one days The rapid recovery, without orbital inflammation, together with his great improvement in general health immediately after the operation all seem to point strongly against any causal relationship between the enucleation and the meningitis

A very important inquiry at this point is as to the possible secondary nature of the eye disease In reviewing the man's history it now seems possible, if not probable, that his severe headache and impaired health may have been due to a low grade of meningitis, and that I was at fault in regarding the head symptoms as entirely due to his severe eye disease Although I did not suspect any cerebral complication, nevertheless the treatment directed for his relief viz —local blood letting, the calomel and soda purge, potas iod et bromid, and later mercurial inunctions were well devised to relieve a meningitis had they been directed with that purpose in view Certainly they afforded him prompt relief from his very severe pain both in head and eye

The absence of orbital symptoms at the onset of the meningitic symptoms affords but little comfort, since in only four of the cases as far as I can find was there any inflammation or irritation of the orbital tissues present, while in many more it is distinctly stated that no connection could be traced The inflammation of the optic nerve and its sheaths is noted in four cases, three of which are the same as noted with orbital inflammation The report of Drs Ellet and Parker shows that in my case also the optic nerve was in a state of active inflammation as far back as the specimen extended Whether this process had invaded the eye from within the cranium or had invaded the brain from the eye must forever remain in doubt I am free to say that I incline to the first, for the reason besides those already stated that the symptoms which ushered in the fatal illness were the same as those I had observed in the hospital before the excision

It must be remembered, however, on the other hand that all the conditions were here present which have in these cases seemed to favor the production of this disease There was the inflamed and suppurating ball, and more than all a ball which had been recently opened, a condition, as has already been pointed out, which was present in nearly all of the reported cases where it was mentioned at all

INTRA-OCULAR INJECTIONS OF SOLUTIONS OF VARIOUS ANTISEPTIC SUBSTANCES, AN EXPERIMENTAL INQUIRY

Read before the Section on Ophthalmology at the Forty fourth Annual Meeting of the American Medical Association

BY G E DE SCHWEINITZ, M D
CLINICAL PROFESSOR OF OPHTHALMOLOGY, JEFFERSON MEDICAL COLLEGE, PROFESSOR OF OPHTHALMOLOGY PHILADELPHIA POLICLINIC OPHTHALMIC SURGEON, PHILADELPHIA AND CHILDREN'S HOSPITALS

A number of researches have been published concerning the effect of the introduction of various substances, solid and liquid, into the vitreous chamber. These may be summarized as follows

1 The introduction into the vitreous of foreign bodies (pieces of wire, lead, glass, etc), or of irritating liquids (croton oil, tincture of iodin, etc) , 2, the injection of sterilized blood into the vitreous humor, 3, intra-ocular injections of various antiseptic liquids [1]

Researches belonging to the first class, from the time of the publication of Pagenstecher's essay on the pathology of the vitreous[2] to Leber's superb work,[3] are chiefly concerned with the behavior of the vitreous towards these foreign substances, and with the complex problems which surround the pathology of inflammation Researches of the second class, which date from the imperfect experiments of Legros,[4] to the thorough investigation of the subject of blood injections into the vitreous by Probsting,[5] have been undertaken to study the deportment of the retina under these circumstances, and to add to our knowledge of the mechanism of retinal detachment and the production of proliferating retinitis. Researches of the third class have been conducted chiefly to test the therapeutic value of the injection of antiseptic fluids directly into the vitreous of an inflamed eye, for example, one suffering from hyalitis, or from sympathetic ophthalmitis, or to try their efficacy in preventing an inflammation of this character after the eye has been exposed to the influences likely to produce it

Abadie,[6] in 1890, suggested the propriety of injecting 2 drops of a solution of sublimate, 1 to 1000, into a wounded eye which has caused sympathetic ophthalmitis of the other eye, which should also be treated with a similar injection directly into the vitreous humor According to him, these injections were of use in checking and ameliorating the inflammatory process Subsequently he published[7] three cases of sympathetic ophthalmitis cured by intra-ocular injections of corrosive sublimate, the strength of the injections being in two instances 1 to 1000 and in one 1 to 500

---

[1] Experiments to determine the effects of injections into the anterior chamber for example those performed by Nuel (Revue Générale d Ophthalmologie T viii, 1889 p 343) do not belong to the present classification As Dr Berry pointed out injections into the anterior chamber and into the vitreous can scarcely be compared

[7] Nouveaux cas d'Ophthalmie Sympathique, Guéri par les Injections intra oculaires de Sublimé Annales d'Oculistique Vol civ, 1890, p 229

In the discussion of a paper communicated by Darier, Abadie's Chief of Clinic, to the French Society of Ophthalmology, on the 8th of May, 1891,[8] concerning sub conjunctival injections of sublimate in ocular therapeutics, the question of intra ocular injections of the same drug received attention, Wecker regarding the transition from intra-ocular to sub conjunctival injections as a decided advance, and doubting the efficacy of the former method of administration In the close of the discussion, Abadie expressed himself as willing to abandon the intra ocular injections of sublimate for sub conjunctival injections, provided it is demonstrated that they are more efficacious, inasmuch as certain observers have doubted their efficacy and, moreover, have not merely been disappointed in their results, but have seen positive harm follow

Occasionally reports of successes from the use of Abadie's treatment of migratory ophthalmitis have appeared in the journals, for example, Baquis[9] reports a remarkable case of this character a woman aged 26 years sustained an injury of the left eye, resulting in an adherent leucoma At the end of three months chronic irido cyclitis produced sympathetic ophthalmitis in the left eye The author then injected 3 drops of a sublimate lotion, 1 to 500, into the sympathizing eye Marked improvement occurred At the end of eight days the injection was repeated, but there were also twelve mercurial frictions, which caused the absorption of the exudates in the pupillary field, showing that there was an intense neuro retinitis in the sympathizing eye At the end of six months the cure continued This author states that he was encouraged to use Abadie's method, not only by the results obtained by the reporter, but on account of the researches of Dr Ovio of Padua, on the intra-ocular circulation and the nutrition of the vitreous This experimenter definitely asserts that weak sublimate lotions may be injected into the vitreous without causing chronic lesions, and without causing the vitreous to diminish in any way the microbicidic power of the sublimate lotions, no matter how weak they may be

Darier[10] states that he has experimented in 1889, on rabbits with the intra ocular injections of "various substances," and that in studying daily the modifications produced by the substances on the vitreous body and the deep membranes of the eye, he was struck by observing how promptly the solutions thus introduced were absorbed without causing excessive disturbance, provided they were very dilute The character of the substances is not described in the paper to which reference has been made

At a meeting of the Ophthalmological Society of the United Kingdom, Nov 10, 1892, Berry[11] gave an account of some facts elicited by experiments on rabbits, undertaken by his assistant, Dr Chassaud, with the object of ascertaining the effect of different solutions injected into the vitreous Unfortunately the details of these experiments are not at hand, but in the abstract given the following results are recorded in some cases, before injecting the antiseptic, the vitreous was inoculated with fresh septic pus The only substance injected after inoculation which seemed capable of preventing purulent hyalitis was chlorin water, and this injection was better tolerated by the retina and vitreous than other strong antiseptic fluids In two cases of purulent hyalitis in man, chlorin water injected into the vitreous led to immediate improvement and the eyes were saved, although sight had been lost before treatment was adopted In the discussion which followed, Griffith suggested the propriety of the use of trichlorid of iodin as an intra ocular injection—an antiseptic, as is well known, which has been much lauded by Pfluger and others in France Berry expressed the belief that the use of intra-ocular injections was a distinct advance in ocular therapeusis, and Mr Hartridge, referring to cases which frequently occurred where the injection of a germicidal solution was evidently indicated, thought that if this method could be demonstrated to be a safe one, a very desirable addition to occular therapeutics would be made

Therefore, both from the clinical and the experimental standpoint, it is desirable to add new data Those which I present are entirely experimental and comprise

1 The injection into the vitreous chamber of rabbits of various antiseptic substances, namely, bichlorid of mercury, 1 to 500, 1 to 1,000 and 1 to 5,000 respectively, cyanuret of mercury 1 to 1,000, aqua chlorinata, officinal strength, blue pyoktanin 1 to 1,000 and trichlorid of iodin 1 to 1,000

2 The injection into the vitreous chamber (dogs and rabbits) of an emulsion of staphylococcus pyogenes aureus of the sixth generation, and after the development of purulent hyalitis the injection of antiseptic fluids (bichlorid of mercury and aqua chlorinata)

3 The simultaneous injection of the staphylococcus emulsion and the antiseptic fluids

FIRST SERIES

Experiment 1—2, 8, 1893 Full grown, slate-colored rabbit. Five minims of bichlorid of mercury solution, 1 to 500, injected into the vitreous 2, 9, 1893 Vitreous cloudy, and at the upper portion somewhat in the position of the injection, a large, dark cloud and a smaller detached one lower down 2, 20, 1893 No change in the permanent lesion of the vitreous

Experiment 2—2, 17, 1893 Full grown, black rabbit Five minims of bichlorid of mercury, 1 to 1,000, injected into the right vitreous, 2 20, 1893 Vitreous cloudy 2, 24, 1893 Vitreous entirely opaque, practically no reflex from the fundus, 3, 1, 1893 Rabbit killed and eye placed in Muller's fluid

Microscope—Choroid edematous, retina practically indistinguishable, being merged into a tissue composed of round and oval cells, well developed fibers and blood channels, through the outer layers of which are freely scattered oval and round densely pigmented cells Additional areas of blood corpuscles and patches of granular débris are visible

Experiment 3—2, 17, 1893 Full grown, white-nosed Maltese rabbit Five minims of bichlorid of mercury, 1 to 1,000, injected into the right vitreous 2, 20, 1893 Large, greenish-white cloud occupying vitreous 2, 24, 1893 Similar appearances, giving somewhat those presented by connective tissue formation in vitreous 3, 6, 1893 Eye removed and placed in Muller's fluid Ophthalmoscopically the vitreous was occupied by a huge whitish mass covered with reddish spots, probably hemorrhages, and giving the impression of extensive detachment of the retina

Microscope—Fine granular débris in anterior chamber, remains of vitreous granular, but no connective tissue.

[11] Intra ocular Injections of Antiseptic Solutions Ophthalmic Review, December, 1892

formation Choroid imperfect and detached (section, however, broken somewhat, hence possible fault in technique), retina extensively detached, in places normal in structure, but in others proliferation of Mueller's fibers (connective tissue framework) passing into vitreous and forming a delicate network of fine fibers (Compare results obtained by Probsting loc cit page 139) The lesions are analogous to proliferating retinitis

Experiment 4—2, 17, 1893 Full grown, gray rabbit Five minims of bichlorid of mercury, 1 to 5,000, injected into the right vitreous 2, 20, 1893 Large, dark cloud occupying vitreous No change before rabbit's death, four days later

Experiment 5—5, 5, 1893 Full grown, buff colored rabbit Two minims of bichlorid of mercury, 1 to 500, injected into left vitreous Immediately afterwards two air bubbles and a small circular cloud visible with ophthalmoscope 5, 9, 1893 Dark opacity in the vitreous up and out, stationary, and resembling a fly's wing The rest of the vitreous clear 5, 11, 1893 Opacity in the vitreous unchanged 5, 17, 1893 Previously described opacity remains stationary Slight general haze in the vitreous 5, 29, 1893 Rabbit dead No change in the opacity

Experiment 6—Large, buff colored rabbit (pregnant) Two drops of bichlorid of mercury, 1 to 500, injected into the left vitreous Immediately afterwards a dark streak marking the track of the needle, a small dark cloud just in the center of the vitreous 5, 9, 1893 Circular opacity in the vitreous with small, central spot The rest of the vitreous clear 5, 11, 1893 The large circular opacity, with a smaller dark center described in previous note unchanged The remainder of the vitreous clear 5, 17, 1893 Opacity in the vitreous of dense white color, shaped like two superimposed rings, rest of vitreous clear 6 1, 1893 No change in previously described opacities Rabbit killed and eye placed in Muller's fluid, not yet examined

Experiment 7—2, 17, 1893 Full grown, black rabbit Ten minims of aqua chlorinata injected into left vitreous On withdrawing syringe a large bleb appeared beneath the conjunctiva, and the vitreous seemed to be filled with a cloudy substance and several air bubbles 3, 6, 1893 Extensive clouding of the vitreous, with probable detachment of the retina 3, 20, 1893 Eye placed in Muller's fluid, no change, other than deepening of opacity, having occurred

Microscope—Choroid for the most part in place, but edematous, prolapse at point of entrance of needle Retina extensively detached and scarcely recognizable, being associated with a band of tissue fiber and round and oval cells and inflammatory material extending from nerve entrance to anterior portion of eye

Experiment 8—2, 17, 1893 Full grown, white nosed Maltese rabbit Ten minims aqua chlorinata injected into left vitreous 3, 6, 1893 Vitreous has remained clear, that is, there have been no dark opacities or white infiltrations and the eyeground is visible without apparent change in the retina 3, 20, 93 Eye placed in Müller's fluid, but not yet examined

Experiment 9—2, 17, 1893 Full grown, gray rabbit Ten minims of aqua chlorinata injected into left vitreous 3, 6, 93 Extensive white clouding of the vitreous, and probable detachment of the retina 3, 20 1893 Eye placed in Müller's fluid, but not yet examined

Experiment 10—3, 8, 1893 Full grown, white and gray rabbit Ten minims of aqua chlorinata injected into right vitreous 3, 11, 1893 Cornea hazy and no view of fundus (Probable contamination from imperfect sterilization of needle

Experiment 11—3, 8, 1893 Full grown white and gray rabbit Five minims of aqua chlorinata injected into right vitreous 3, 11, 1893 Large, greenish white opacity well forward in the vitreous, giving the appearance of an old detachment of the retina, and connective tissue formation in vitreous No change before rabbit's death, three days later

Experiment 12—3, 8, 1893 Full grown white and gray rabbit Ten minims of aqua chlorinata injected into right vitreous 3, 11, 1893 Large greenish-white opacity obscuring the entire vitreous Eye removed and placed in Muller's fluid

Microscope—Retina and choroid for the most part in place and of fairly normal appearance, but well forward on right side a circumscribed detachment of retina, the space between retina and choroid being filled with a granular material (coagulated vitreous) containing a number of hypertrophied vitreous cells

Experiment 13—4, 17, 1893 Full grown black rabbit Ten minims of aqua chlorinata injected into right vitreous Immediately afterwards a large air bubble surrounded by a dark cloud 4, 20, 1893 Circular white opacities and still some air bubbles present in the vitreous 4, 28, 1893 Several large, white opacities hanging in the vitreous surrounded, however, by clear vitreous, permitting a view of the fundus No hemorrhages in the retina and no detachment 5, 9, 1893 Practically no change from note under 4, 28, 1893 5, 17 1893 Irregular, dense, white opacities scattered throughout the retina, between which the fundus is dimly seen, with evident patches of choroiditis down and out 6, 1, 1893 No change from above Eye removed and placed in Muller's fluid, but not yet examined

Experiment 14—4, 17, 1893 Full grown black rabbit Ten minims of aqua chlorinata injected into right vitreous Immediately afterwards numerous air bubbles surrounded by a cloud 4, 20, 1893 Streaks of dark opacity and clouding the vitreous, partially obscuring the fundus 5, 4, 1993 Entire vitreous opaque and whitish Lens beginning to be cataractous 5, 9, 1893 Diffuse opacity of the entire vitreous, presenting the general appearance of a white cataract 5, 11, 1893 Eye removed and placed in boro-glycerin, but not yet examined

Experiment 15—2, 20, 1893 Full grown white and gray rabbit Five minims of cyanuret of mercury, 1 to 1,000, into right vitreous 2, 24, 1893 Vitreous cloudy and eyeground invisible No change before rabbit's death

Experiment 16—2, 20, 1893 Full grown white and gray rabbit Five minims of cyanuret of mercury, 1 to 1,000, injected into right vitreous 2, 24, 1893 Vitreous cloudy and streaked, but appearances of whitish masses and detachment of the retina lacking No clearing of vitreous before the rabbit's death, three days later

Experiment 17—Five minims of cyanuret of mercury, 1 to 1,000, injected into left vitreous Immediately afterwards dark streaks in vitreous and several air bubbles 3, 11, 1893 Vessels of the retina visible, but the vitreous hazy and streaked Rabbit dead two days later, without change

Experiment 18—3, 8, 1893 Five minims of cyanuret of mercury, 1 to 1,000, injected into left vitreous Immediately afterwards dark streaks in vitreous and several air bubbles 3, 11, 1893 Vitreous shows large, greenish white opacity obscuring the fundus Eye removed and placed in Muller's fluid

Microscope—Choroid edematous, retina much broken and detached, due to imperfect technique, typical prolapse of choroid into wound made by entrance of needle The internal portion of the puncture is closed with granular pigment cells from the choroid, beyond is a tissue composed of round and oval cells (granulation tissue) capped at the scleral orifice with pigment granules

Experiment 19—3, 8, 1893 Full grown gray and white rabbit Exact repetition of Experiment 16

Experiment 20—4, 17, 1893 Full grown black rabbit Five minims of cyanuret of mercury, 1 to 1,000, injected into left vitreous Immediately afterwards a large air bubble surrounded by a dark cloud 4, 20, 1893 Whitish and darkish opacities in the vitreous partially obscuring the retina 4, 28, 1893 Vitreous opaque and whitish 5, 9, 1893 Scattered whitish opacities throughout the vitreous obscuring any view of the fundus 5, 17, 1893 Entire vitreous opaque, of a dense white color

Experiment 21—4, 17, 1893 Full grown black rabbit Five minims of cyanuret of mercury, 1 to 1000, injected into left vitreous 4, 20, 1893 Whitish and grayish opacities in vitreous, largely obscuring the retina 4, 28, 1893 Entire vitreous filled with an irregular whitish mass covered with hemorrhages 5, 9, 1893 Practically no change from note under 4, 28, 1893, except that in the upper and the inner portion of the vitreous there is a break in opacity, permitting a red reflex from the fundus 5, 11, 1893 Eye removed and placed in Muller's fluid

Microscope—Choroid detached, retina not distinguishable, being bound up with extensive tissue formation in vitreous composed of young fibrous tissue, inflammatory cells, pigment cells and blood corpuscles

Experiment 22—5, 11, 1893 Large buff colored rabbit (pregnant) Two minims of trichlorid of iodin injected into right vitreous Immediately afterwards two air bubbles and a small ring of opacity visible with the ophthalmoscope 5, 17, 1893 Large circular opacity of dense white color with a clear center directly in the center of the vitreous, the rest of the vitreous clear 6, 1, 1893 Circular opacity described above, with strands of similar color passing in several directions through vitreous Eye removed and placed in Muller's fluid, but not yet examined

Experiment 23—5, 11, 1893 Full grown buff-colored rabbit

Five minims of blue pyoktanin, 1-1000, injected into right vitreous Immediately afterwards a small purple cloud visible in the center of the vitreous 5, 17, 1893 Irregular dark opacity up and in, and the entire vitreous of a faint, purplish hue No detachment of the retina 6, 1, 1893 No change before rabbit's death, two days ago

SECOND SERIES

Experiment 1—2, 8, 1893 Full grown albino rabbit Five minims of an emulsion of staphylococcus pyogenes aureus of the sixth generation injected into right vitreous 2, 9, 1893 Some purulent conjunctivitis, entire cornea hazy, iris dimly visible below in the upper and inner portion of the cornea and yellowish, purulent mass Five minims of bichlorid of mercury injected directly into the vitreous 2, 10, 1893 Much increase in the purulent keratitis Eyeballs soft Germicidal injection repeated 2, 17, 1893 Rabbit dead from general infection

Experiment 2—2, 24, 1893 Full grown white and gray rabbit Production of extensive hypopyon keratitis and probably purulent hyalitis by emulsion of staphylococcus Five minims of bichlorid of mercury 1-5000 injected without result Rabbit dead from general infection

Experiment 3—2, 8, 1893 Large mongrel poodle, full grown Five minims of emulsion of staphylococcus injected into right vitreous 2, 9, 1893 Slight conjunctivitis, cornea hazy and pus in the central layers No view of fundus Ten minims of bichlorid of mercury 1-500 injected into vitreous 2, 10, 1893 Extensive purulent keratitis, the eye soft, injected, and apparently in a state of panophthalmitis Germicidal injection repeated 3, 8, 1893 No further treatment was given to the mongrel poodle except to wash his eye with warm water The conjunctivitis gradually disappeared and the eyeball lost its inflammation At this date the eye is quiet, slight injection of the episcleral vessels no pus anywhere visible, the cornea hazy in its lower portion, but the iris visible above, being a result entirely unexpected after the injection of the staphylococcus

Experiment 4—2, 20, 1893 Gray and white rabbit Five minims of staphylococcus emulsion injected into right vitreous 2, 21, 1893 Five minims of bichlorid of mercury, 1 500 injected 2, 24, 1893 Purulent ulcer and hypopyon and the rabbit dead of general infection

Experiment 5—2, 20, 1893 Full grown rabbit Exact repetition of Experiment 4, with the same result

THIRD SERIES

Experiment 1—2, 27, 1893 Full grown black rabbit Five minims of staphylococcus emulsion injected into right vitreous, immediately followed by 5 minims of bichlorid of mercury, 1 500 3, 1, 1893 Cornea infiltrated and a large quantity of pus in its lower portion 3, 6, 1893 Entire cornea red, pus filling the anterior chamber 3 10, 1893 Eye intensely hyperemic, extensive hypopyon No ultimate improvement

Experiment 2—2, 27, 1893 Full grown tan and white rabbit Five minims of staphylococcus emulsion injected into right vitreous, immediately followed by 10 minims of cyanuret of mercury, 1-1000 3, 1, 1893 Cornea cloudy and infiltrated No view of the eye ground 3, 6, 1893 Large mass of the appearance of lymph filling the anterior chamber and giving the impression of spongy iritis 3, 10, 1893 Extensive hypopyon keratitis with purulent conjunctivitis No ultimate improvement

Experiment 3—2, 27, 1893 Full grown gray rabbit Two minims of staphylococcus emulsion, immediately followed by an injection of 10 minims of aqua chlorinata, into the right eye 3, 6, 1893 Hypopyon keratitis 3, 10, 1893 Entire cornea cloudy and infiltrated, and pus filling the entire anterior chamber Eyeball removed and placed in Muller's fluid

The thirty-one experiments which comprise this research may be summarized as follows

Normal Eyes—There were six injections with bichlorid of mercury, the dose varying from 2 to 5 minims, in all, permanent lesions visible with the ophthalmoscope were produced in the vitreous, two eyes examined with the microscope showed extensive new formed connective tissue in the vitreous, together with detachment of the choroid and retina on the one hand and, on the other, lesions indicating an early stage of proliferating retinitis

There were eight injections with aqua chlorinata, the dose varying from 5 to 10 minims, in all, permanent vitreous lesions were produced, except in one (Experiment 8), in which the vitreous remained clear, that is, there were no well-formed dark opacities, or white areas of infiltration One eye in this series was contaminated by imperfect sterilization of the syringe Two eyes were examined with the microscope, and showed in one after thirty-one days had elapsed, extensive detachment of the retina and *the formation of a band of tissue composed of young* cells and fibers constituting the so-called inflammatory material, which passed from the optic nerve entrance through the entire vitreous, and in the other a circumscribed detachment of the retina three days after the injection

There were eight injections with cyanuret of mercury, the dose being 5 minims in each, and causing in every instance positive lesions in the vitreous demonstrable with the ophthalmoscope in the form of more or less dense opacities Two eyes examined with the microscope showed in one detachment of the retina, hernia of the choroid into the wound produced by the puncture with the needle, causing traction on this membrane, and in the other twenty-five days after injection, extensive tissue formation in the vitreous of the type previously described

There was one injection of trichlorid of iodin, the dose being 2 minims, resulting in dense opacity of the vitreous There was one injection of blue pyoktanin, resulting in a purplish discoloration of the vitreous, and a cloudlike opacity

Pathological Eyes—In the first series there were five experiments—four rabbits and one dog—purulent hyalitis going on to purulent ophthalmitis, having been produced by staphylococcus emulsion. The inflamed eyes were treated by injections of bichlorid of mercury directly into the vitreous, the dose being 5 and 10 minims, and varying in strength from 1 500 to 1-5000 The rabbits failed to show any signs of amelioration, and died from general infection The dog showed no improvement at first but gradually improved, and one month after the last injection, only two having been given, was discharged with the eye comparatively quiet, a moderately dense macula being all that remained of an inflammation which at its height gave evidence of the most extensive purulent kerato iritis, probably ophthalmitis

In the second series there are three experiments, all rabbits, who received a simultaneous injection of staphylococcus emulsion and 5 minims of bichlorid of mercury 1-500, 10 minims of cyanuret of mercury 1-1000, and 10 minims of aqua chlorinata officinal strength respectively In no case was there the slightest improvement The eyeball of Experiment 3 treated with aqua chlorinata was examined with the microscope and showed purulent infiltration of all of the coats of the eye—in other words, an acute panophthalmitis Hence it is evident that in the normal eyes injected with solutions of various antiseptic substances, only one escaped positive permanent lesion easily visible with the ophthalmoscope, and situated usually in the vitreous, more rarely in the choroid and retina This exception occurred with aqua chlorinata, and is so unexpected a result that suspicion is not lacking that there may have been failure to introduce the drug as thoroughly as in the other eyes, although there is no note as to any imperfection in the experiment It is mentioned, however, because as will be remembered, Dr

Berry has found that chlorin water was better tolerated by the retina and vitreous than other strong antiseptic fluids.

These experiments certainly fail in confirming the observations of Ovio, that weak solutions of sublimate may be injected into the vitreous without causing chronic lesions; that is to say, a solution of 1-5000 will produce as much disturbance as a lotion of 1-500. It seems evident from the experiments that under any circumstance more would depend upon the dose of the drug injected than upon the strength of the solution used. Two minims seem to be much less likely to cause a general clouding of the vitreous than 5 or more minims, but none the less, even in this small dose, in each instance they caused a chronic and dense vitreous opacity. In addition to the lesions which are so evident with the ophthalmoscope, the microscope shows that they were not confined alone to the vitreous, and that others, not ordinarily detectable, were present. Thus, according to circumstances, we deal with edema and rarefaction of the choroid, sometimes with its detachment, with detachment of the retina and a type of retinitis analogous to that which is designated proliferans, and with connective tissue formation in the vitreous of extensive character. Not only this, but it is interesting to note that in two of the punctures examined there was well-marked hernia of the choroid. How much such incarceration of this membrane would add to the danger of the treatment it is difficult to decide. It is suggestive of the fact that other punctures in operative surgery in this region may be followed by a similar result.

The entire failure to check the purulent inflammation called into existence by staphylococci emulsion, by injecting into the vitreous strong solutions of bichlorid of mercury, or to prevent its occurrence by a simultaneous injection of a solution of bichlorid of mercury, cyanuret of mercury, or aqua chlorinata, is instructive, as showing an indifferent therapeutic power on the part of these injections; but it should be remembered in all fairness, that the inflammation was exceedingly active, that the number of experiments is comparatively few, and that the animals used were rabbits, whose well-known susceptibility to all agents that cause suppuration render them peculiarly liable to the activities of the staphylococci, and equally difficult to impress with counteracting remedies. The apparent cure of the mongrel cur is interesting as an isolated fact, but can not be accepted in strong confirmation of the treatment chiefly because it is a single experiment and needs confirmation. In fact, to test the therapeutic value of these injections, dogs should be submitted to a similar series of experiments.

The evident conclusion of the whole matter, from the experimental standpoint of the present research is, that the vitreous, choroid and retina withstand badly intra-ocular injections of various antiseptic solutions; that these injections in rabbits have no influence in preventing or checking a purulent inflammation originated by staphylococci injection; that in a dog intra-ocular injections of bichlorid of mercury were followed by the cure of a purulent ophthalmitis; that if the drugs are to be employed, the dose should be a small one, probably not more than 2 minims, in this respect conforming with Abadie's original recommendation.

DENDRITIC KERATITIS

Read in the Section on Ophthalmology at the Forty Fourth Annual Meeting of the American Medical Association

BY WM. H. WILDER, M.D.

PROFESSOR OF OPHTHALMOLOGY, CHICAGO POLICLINIC; PATHOLOGIST AND ASSISTANT SURGEON TO THE ILLINOIS CHARITABLE EYE AND EAR INFIRMARY, ETC.

In 1871, at the Heidelberg Ophthalmological Congress, Horner[1] described a disease of the cornea characterized by the appearance of numerous vesicles arranged in groups, accompanied by severe pain, photophobia, lachrymation and conjunctival irritation coincident, in many cases with herpes febrilis of the nose, lips, eyelids and other parts of the face. In the thirty-one cases observed by him, there was in every case some catarrhal inflammation of the respiratory passages, and in twenty-eight there was present a herpes of the nose or lips. To this affection Horner gave the name, "herpes febrilis corneæ."

Inquiry as to the cause of this condition has been further prosecuted by subsequent writers, notably by Mlle. Kendall,[2] a pupil of Horner, who in 1880, analyzed 115 cases from the Zurich clinic.

These were differentiated from Zoster and classed as herpes febrilis. As to the general diseases that were held to have some causal relation to the corneal affection, coryza, catarrh, or cough preceded or coexisted with thirty-six, pneumonia with thirteen, passing chill and fever eleven, intermittent fever three, rheumatism two, gastric catarrh two; hay fever, typhoid, toothache, whooping cough, cessation of a chronic discharge of nose, erysipelas each caused one case; two occurred while patients were in childbed; some mild illness accounted for three; while in thirty seven there was no existing malady or assignable cause for the herpes of the cornea.

With these observations accord well the opinion of Godo[3] who attempted to differentiate a symptomatic and an idiopathic form of the malady; in the former of which there was a period of general illness followed by the appearance on the cornea of vesicles which, breaking down, left small ulcers. Godo observed that malarial infection was present in nearly one third of his cases, and ascribed to it the cause of the corneal herpes. Still later, Haab, who succeeded Horner in Zurich, Fuchs, Adler and others have noticed the frequency of herpes of the cornea following influenza. A valuable contribution to this subject is an inaugural thesis by Wangler,[4] which appeared in 1889, and contains a study of all the cases, 150 in number, that had been observed in the Zurich clinic since 1871. This number shows nearly 4 cases to each 1,000 patients (about 0.37 per cent.), which indicates that the affection is not so rare as has been commonly supposed.

In the Ophthalmological Section of the Eighth International Congress of Medicine at Copenhagen in 1884, Hansen-Grut[5] reported a condition of the cornea which he termed "dendritic keratitis." He describes it as "a superficial ulceration with a chronic course and a tendency to become serpiginous." It begins with slight pain and conjunctival injection. The epithelium ulcerates rapidly and during the whole course of the malady, the pain, injection and photophobia are comparatively insignificant "The ulceration continues to propagate itself, '*dans tous les sens*,' by means of buds or excrescences, so that the line of demarcation of the ulceration, which remains very superficial during the whole course, becomes very irregular The surrounding parts remain perfectly clear and the cornea does not become vascular This affection must not be mistaken for vesicular keratitis It is in no way connected with frontal herpes, nor with herpes accompanying bronchial catarrh or pneumonia, the form so well described by Horner" In a later communication, he differentiates dendritic keratitis from herpes cornea and says "In the former there is no question of vesicles, and in no case was there any previous disease that could have occasioned an herpetic eruption"

Somewhat later, Emmert,[6] apparently without a knowledge of the contribution of Hansen-Grut to the subject, recorded and described six cases of a new affection, which seems from the description to be similar in nature to those seen by the latter author In these cases there was a form of ulcerative keratitis beginning as a point of grayish sub-epithelial opacity, from which branches were thrown out, these in turn dividing and throwing off branches to either side The ulceration was progressive but remained superficial and was accompanied by more or less photophobia, lachrymation and redness of the conjunctiva On examination of scrapings from the furrows he found bacilli

While both writers suspected that the malady was of mycotic origin, Emmert believed it to be connected in some way with the scrofulous and tuberculous diathesis, but Hansen Grut denies this influence Emmert observed in a number of his cases that the point of departure was an ulcer, possibly from some abrasion, or from a foreign body on the cornea, which seemed to furnish the door of entrance for the microorganisms Both these writers appear to have been unaware of the fact that Chas J Kipp[7] of Newark, N J, in 1880, four years previous to the announcement by Hansen-Grut of the discovery of a peculiar dendritic form of ulceration of the cornea, had read a masterly article before the American Ophthalmological Society, describing an affection which, in its salient features is remarkably similar to that recorded by the Danish observer, but ascribing the cause to malarial infection "This ulceration," he says, "is commonly first noticed shortly after an attack of intermittent fever, often simultaneously with the appearance of herpetic vesicles on the nose and lips In a number of patients who had annual visitations of this fever, each attack was regularly followed by the ulceration of the cornea" The ulceration began with severe pain in and around the eye, especially along the course of the supra-orbital nerve, with circumcorneal injection, photophobia and lachrymation, symptoms which in Hansen Grut's cases were quite insignificant If examined early enough, one or two slightly raised opaque lines were seen on the cornea, which on the following day had increased in length and had been transformed into a shallow ulcer He does not speak of the epithelium being raised to form vesicles The ulcer spread slowly by sending out at places club-shaped, slightly raised, grayish offshoots from its sides which were nothing more than small areas of new infiltration in connection with the original ulcerated area In this way was formed a branching, dendriform ulceration which had a tendency to extend over the greater part of the cornea if not checked

In most of Kipp's cases, the ulcer remained superficial and showed no tendency to extend deeply as in serpiginous infected ulcer, and a hypopyon was rarely seen in connection with it In this respect, as well as in chronicity and the length of time required for complete healing, this ulcerative process resembles that described by Hansen Grut,[8] while in most particulars, the description accords so well with that of Emmert,[9] that one is constrained to believe the process is the same Within the past eight months, three cases of this interesting affection have come under my observation, which although presenting no new features, resemble in some respects all the so called different varieties of this condition

Case 1—J P, age 30, Polish, came to Chicago Policlinic March 30, 1892, with a superficial ulcer of the left cornea which began a few days before as a soreness of the eye There was considerable temporal pain, lachrymation and photophobia On the cornea was seen an ulcer beginning near the upper margin and extending downward, and on each side of it was a little branch or bud that suggested at once dendritic ulceration No history of any recent illness was obtained, but he had suffered from malaria some years ago He was given quinia sulph grs iv t i d The ulcer extended and seemed to become deeper Small offshoots were thrown out from the main branch, but after crossing the central part of the cornea the process ceased and healing took place rather rapidly so that by April 22 he was well

The opacity that remained marked the course of the ulcer (Fig 1) The treatment consisted of instillations of atropin gr iv ʒi, hot applications to relieve the pain, and quinin

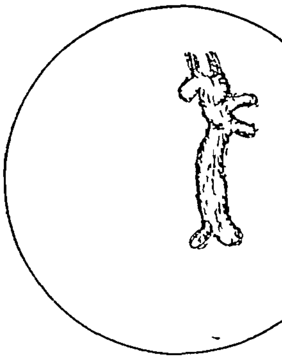

FIGURE 1

Case 2—J G, age 52, was first seen June 15, 1892, at the Chicago Policlinic, when he complained of pain in left eye, with great lachrymation and photophobia Trouble began eleven days before, and had been gradually increasing A superficial ulcer of the cornea could be seen extending from above downward This branch had a small offshoot to the left, and the floor of the ulcer had a grayish appearance There was severe temporal and frontal pain, and pressure upon the supra-orbital nerve and its branches caused excruciating pain Patient had suffered extremely from malaria when in the army, nearly thirty years ago, and since then had had from time to time attacks of neuralgia, malaise, etc, that he attributed to malarial poisoning Cornea was not anesthetic Ocular and palpebral conjunctiva considerably injected Ordered grs x of quinin early in the morning, for the pain seemed to be most severe in the forenoon, atropin and hot applications to the eye Two days later he seemed to be better, and the dose of quinin was diminished

June 25 Ulcer seemed to be spreading downwards, another little bud was seen to the left A few days later as the disease was not checked, the ulcer was cauterized thoroughly with 95 per cent carbolic acid, after dropping into the eye a 2 per cent sol of fluorescein in order to differentiate the ulcerated area, which was then stained green, the healthy cornea remaining uncolored The eye appeared better next day, the upper part of the ulcer had healed, but in a few days the trouble began again, the ulcer gradually creeping around the center of the cornea always remaining superficial, the main stem sending off small branches July 10 it was again cauterized, and Fowler's solution substituted for the quinin, 5 drops three times a day In a few days the ulceration ceased and the cornea soon healed (Fig 2) At no time in the course of the disease, was there any hypopyon or any evidence of inflammation of the iris The opacity that remained some time was not very dense, and when the patient was last seen, seemed to be clearing away rapidly

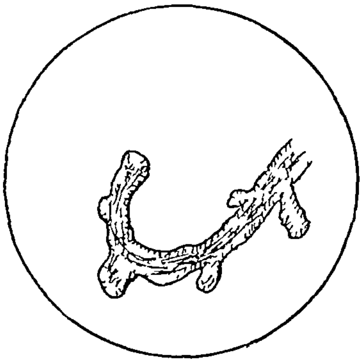

FIGURE 2

Case 3—O H, German, age 24, came under my care at the Cook County Hospital Oct 8, 1892 Had hemorrhage of lungs two years ago, and was inoculated with Koch's tuberculin Has lost flesh lately Had some inflammation of eyes five years ago, and was fourteen days in a hospital Two weeks ago recovered from an illness which was characterized by chill followed by fever and sweating, the paroxysms occurring every second day Present trouble of right eye began two weeks ago with redness, dimness of vision, photophobia, lachrymation, pain and continuous irritation which gradually grew worse On examination the conjunctiva was seen to be somewhat swollen and injected On the surface of the cornea were superficial ulcers arranged in a branching form These minute ulcers had become confluent in some places, while in others they remained separated from each other by a narrow isthmus of unbroken epithelium The instillation of a 2 per cent solution of fluorescein brought out this point very distinctly (Fig 3) During the examination the patient had a severe chill which began at 1 P M, followed by fever (T 105, p 120) and sweating The examination of the blood by Dr Hessert the house surgeon, showed the presence of the plasmodium malariæ Ordered 15 grains of quinin in divided doses that evening, and the same quantity the following morning, after that 5 grains every four hours, atropin and hot applications to the eye Patient improved rapidly, had no return of the chill and in a few days the ulcer was *healed leaving a faint opacity marking the course it had* taken There was no appearance of irritation of the iris

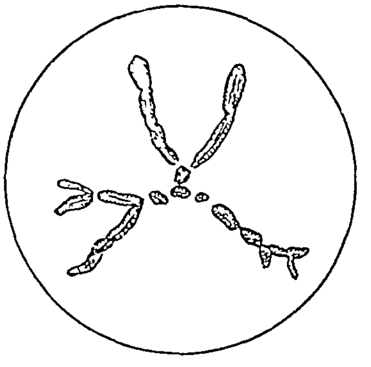

FIGURE 3

Are the different writers who contend that they are describing essential and distinct forms of corneal disease justified in their claims? Can it be proven that the "dendritic keratitis" of Hansen-Grut and the "keratitis dendritica exulcerans mycotica" of Emmert are separate and distinct forms of ulceration as these writers aver, or that Kipp's malarial keratitis is a variety occurring only as a result of miasmatic infection, or must we accept the opinions of Haab, Wangler Kendall and Hagnauer that all these cases properly belong to the class of herpes febrilis originally described by Horner

According to Haltenhoff,[10] to whose article in the *Annales d'Oculistique*, of June, 1892, I am greatly indebted, Hagnauer, in a thesis for his doctorate written in 1891, presumably under the supervision of Haab, complains that during the last twelve years several authors have described as new, forms of superficial keratitis which were so like the herpes of Horner as probably to be the same Hagnauer contends that the cases of Hock (Centralbl f Augenheilkunde, *December, 1885), Macrocki (Klin* monatsbl f Augenheilkunde, Mai, 1890), Gillet de Grandmont (Archiv d'Ophthalmologie, 1887, p 422) belong in the category of herpes febrilis He places also in the same class the cases of Kipp[11] and Van Millingen [12]

In spite of the rarity of intermittent fever in Zurich, five cases are ascribed to this disease. Kipp's[13] experience leads him to believe that malarial fever was the cause of the corneal disease in 90 per cent of all the cases in which the peculiar ulceration was present Furthermore, he thinks the affection is identical with that described by Hansen Grut and Emmert, and does not doubt that it is of a mycotic nature

The contention of the latter authors that in cases of dendritic ulceration there is no question of vesicles does not seem to be well grounded, since most cases would probably present themselves to the surgeon only after the delicate epithelium covering the vesicles had broken down, when only the minute ulcer would be seen Haab has had the opportunity of seeing but one case in which the vesicles were intact The further observation of these writers that in their cases there was no coincident herpes of the face, nor any febrile affection that would be likely to occasion such an eruption, only accords with the forty or more cases of Kendall, and the cases of others in which there was either no previous illness, or it was so slight as to pass almost unnoticed The fact that in some cases the subjective symptoms of pain, photophobia and lachrymation are marked, and in others quite insignificant, certainly does not furnish a very accurate differential sign

That attacks of malarial fever may induce an ulceration of the cornea that assumes a dendritic form, as has been so ably presented by Kipp, is unquestionable, but that the keratitis and the resulting ulceration are the direct result of the malarial poison is to be doubted The fact that in many of Kipp's cases there was a simultaneous eruption of herpes vesicles on the face would point rather to the explanation that the corneal trouble was also herpetic, and that the small vesicles quickly breaking down and becoming confluent, left the irregular *branching ulceration In my third case (Fig 3),* which to my mind was unquestionably induced by the malarial fever, this point seemed to be clearly demonstrated In this case, as shown in the figure, there were some very minute ulcers which seemed to be separated from the others in the branch by a narrow isthmus of unbroken epithelium, suggesting that the branch had been formed by the confluence and breaking down of little vesicles that were adjacent The staining of certain points in the branch more deeply than others with fluorescein, seemed to indicate that these were the points of the original infiltrations That anti-malarial treatment acts well in cases in which there is malarial poisoning has been pointed out by Kipp,[14] Hotz[15] and others, but this can hardly be cited as proof of the direct relation between malaria and dendriform ulceration In Case 2, the exhibition of arsenic in 5 drop doses of Fowler's solution apparently worked like a charm, but I am still in doubt as to whether it was the anti-malarial or the caustic treatment that effected the cure

[13] Trans Amer Ophth Soc, 1889, p 331

Hagnauer observed sixteen cases of herpes corneæ, in a period of six weeks, in patients affected with the grippe, and Hansen,[16] Pfluger,[17] Greff,[18] Eversbursch[19] and others, have recorded cases observed in the last epidemics of influenza, that in appearance simulated keratitis dendritica It seems quite probable that future observations will tend to simplify the pathology of this interesting subject by classifying all dendriform ulcerations as herpes of the cornea, rather than adding the complication of another variety of keratitis

70 State Street

TWO CASES OF BRAIN TUMOR WHERE OPTIC NEURITIS WAS THE ONLY POSITIVE SIGN—AUTOPSIES

Read before the Section on Ophthalmology at the Forty fourth Annual Meeting of the American Medical Association

BY EDWARD P MORROW, M D
OPHTHALMOLOGIST TO AULTMAN HOSPITAL, CANTON, OHIO

Although pathognomonic symptom is a term in medicine, yet taken in its strict interpretation we have no symptom by which we can positively determine a disease without question Taken in its better sense, a characteristic symptom of a disease, we may call optic neuritis a pathognomonic symptom of brain tumor This has been so well established that it needs no discussion The object of this report is not to further establish that fact, but to present two cases where optic neuritis was the first, and up to the time of its discovery, the only positive sign upon which a diagnosis could be based For that reason I take it, brain tumor, with its ophthalmic aspects may be worthy of a discussion here, inasmuch as the ophthalmologist is sometimes called upon to give his opinion and to aid in the diagnosis of a case To give positive or negative evidence as to choked disc may be all that is asked of him, but if he is also able by his knowledge of the relation between choked disc and intracranial diseases to differentiate between abscess, tumor, aneurismal tumor, etc , as well as to give some opinion as to its probable location within the skull, his services will surely be of more value than those of the specialist whose knowledge as well as his practice is limited to the eye

Case 1—Is a lad 17 years of age, well formed and well nourished, of good parentage There is a large family of boys and girls all in good health In April, 1887, he had a fall from a bicycle, striking his head and rendering him unconscious, from which he promptly recovered From that date, however, he was under treatment from time to time, for what his physician supposed to be a general run down state He had no special symptoms except weakness and malaise with occasional dizziness when walking The physician under whose care he was at that time, tells me that at no time did he have any symptoms that led him to suspect any cranial trouble In November, 1887, the family changed physicians and employed Dr James Fraunfelter of Canton, Ohio The boy made occasional visits to his office, complaining mostly of dizziness and occasional vomiting The Doctor suspected some head trouble, but continued to treat him expectantly until in December, when he took to his bed, saying he was too tired to be about Shortly after this he complained that his vision was imperfect and confused My service was asked Dec 15, 1887, to determine the cause of his eye trouble, and if possible shed light upon the diagnosis I found the patient in bed His greatest complaint was that he was tired, did not sleep well, and did not want to exert himself While he had had occasional headaches up to this time, they had not been severe nor localized There was no paralysis or febrile condition An examination of the eyes revealed moderately dilated pupils, that reacted to light rather sluggishly

With such tests of his vision as could be made, it was found that he could read large types and distinguish objects in the room His confusion of vision was probably diplopia, although it was impossible to make tests to prove it Such tests as could be made showed no paralysis of ocular muscles The ophthalmoscope showed at this time a double optic neuritis in the swollen stage, with numerous retinal hemorrhages in the region of the disc The revelation of the choked disc with the history of the head injury and character of the symptoms led at this time to a provisional diagnosis of cerebral abscess in the latent stage The later gradual and uniform development of symptoms changed the diagnosis to that of brain tumor These symptoms were, gradual and increasing pain, localized to right side, vomiting, gradually increasing in frequency Facial paralysis and paralysis of external rectus muscle of right side At no time was there rigor or rise of temperature, nor were the symptoms sudden or rapid, thus excluding any suppurative process During the last week of his illness he had several epileptiform convulsions, except during these, he retained consciousness and a fairly good intellect up to the time of his death, which occurred the last week in January, 1888, five weeks after the ophthalmoscope revealed the optic neuritis

Autopsy—Body fairly well nourished Calvarium removed, external and internal surface of skull normal Calvarium not unusually adherent to dura mater, dura mater hyperemic Surface of brain when dura was removed showed no abnormality or asymmetry No unusual amount of fluid in arachnoidal space Brain removed without membranes The optic nerves when exposed showed to sight and touch no unusual appearance Longitudinal sections of the brain were made from above downwards The tissues were normal in appearance and consistency until the temporal lobe of right side was reached, here the tissues began to soften from above downward until a glioma pear shaped, amber in color, soft and somewhat commingled with the cerebral substance was found, lying at the base of the middle lobe Its long axis, more than two inches, was directed backward and inward The large end, over an inch in diameter, was backward and within the temporo-sphenoidal lobe, the small end forward and outward

Case 2—Also a young man, 19 years of age The history I obtained is imperfect, as he was living in the country and did not consult any physician early in his trouble When he did, he went the rounds of all of them, so that it is impossible to get any connected report In November, 1892, he came into the hands of Dr J F Marchand of Canton Ohio, with whom I saw the case, and to him I am indebted for the following history of symptoms he first complained early in the summer of 1892 of an unsteadiness of gait, this continued until late in the summer, but was not sufficiently annoying for him to seek advice Later, however, he had seasons of vomiting, and for this he saw a number of physicians without relief In September of the same year he took to his bed, not because of any inability to be about, but apparently from the beginning of a lethargy which continued to develop and from which he never could be wholly aroused When I first saw him in November, 1892, he was vomiting considerably and had by this time become somewhat emaciated His intellect was dull, his condition was passive in the extreme He answered questions in short, shouting monosyllables, yes or no It took him considerable time to understand what was said to him, but when he did understand, his answers were intelligent and correct He complained of some headache, but it was seldom severe, and at this time not localized The first examination of the eyes made at this time revealed widely dilated pupils Eyes straight Tests showed remote and proximate vision normal The media were clear and fundus normal, except considerable hyperemia of the disc, which by subsequent examinations proved to be commencing optic neuritis Under treatment with bromids and ergot his vomiting ceased for quite a period and his condition somewhat improved

[14] Op cit
[15] Chicago Med Journal and Examiner December, 1881
[16] Hospitals Tidende 1891
[1] Reviewed in Annales d'Oculistique Fev 1892
[18] Berlin Klin Wochenschrift Nr 27, 1889, Ibid
[19] Münch Med Wochenschrift S 89 1889

A subsequent examination made January 15, 1893, showed a double optic neuritis in the swollen stage, with numerous hemorrhages in the retina There was still considerable vision, as he was able to read a typewritten address on an envelope and other such tests as could be obtained There was no paralysis of any muscle of the body, and at no time up to the time of death did any develop The subsequent history is one of constant decline Emaciation became extreme, although he ate largely and vomited but little Toward the end he became blind, developed the cephalic cry and was reduced to imbecility On the morning of March 12, 1893, he ate a hearty breakfast and died almost instantly afterwards

Necropsy—Body greatly emaciated, calvarium removed, membranes anemic, no arachnoidal fluid, brain removed without membranes, surface of brain showed no asymmetry, but bloodless Sections of brain made horizontally from above downward, nothing abnormal except anemic condition until ventricles were opened These were enormously enlarged and distended with fluid Further sections of the cerebrum showed no evidence of lesion When the cerebellum was examined a tumor, disc shaped, about one half inch in thickness and two inches in diameter, was observed upon the superior surface of the cerebellum, covering the superior vermiform process and extending about equally over each lateral hemisphere The tumor was a soft glioma and broke down under slight pressure An examination of the optic nerves showed nothing abnormal to sight or touch

Among the points of interest, those especially claiming attention are I think, 1, that the ophthalmoscope was the first to give objective and positive evidence of a cerebral lesion in either case, 2, the obscurity of the symptoms and the similarity in both cases of cerebral abscess in the latent stage In Case 1, a positive diagnosis was not made until late, on account of the head injury being taken as a cause of abscess In Case 2, a diagnosis of brain tumor was made, not because of any uniform symptoms of brain tumor, but because of the absence of any ascertainable cause of an abscess, 3, the location of the tumor Tolerance of the nerve elements of the temporal lobe has been shown many times in abscess following injury or ear diseases Tolerance is also shown in Case 1 to a tumor in the same location until it reached considerable size, when by encroaching upon the sixth and seventh cranial nerves, strabismus and facial paralysis resulted

In Case 2, the remote position from intracranial nerves would account for the absence of paralysis of parts supplied by them The mental condition in Case 2 was due, not to the location of the tumor primarily, but in all probability to the great distension of the central cavities of the brain and the consequent anemia, with its effect upon the nutrition of the elements We find, however, in both cases, that while the other intracranial nerves tolerated the neoplasm, that the optic nerve succumbed to inflammation

A point of interest in the autopsy is the absence of fluid in the arachnoidal space in both cases, as well as the apparent normal state of the optic nerves to the unaided senses No microscopic examination of the nerves was made to determine the condition of the sheath or intervaginal space

Of the two prominent theories advanced for choked disc, namely, the lymph space and the vasomotor paralysis theory I can not see that these cases add to or subtract from either Certain it is that our knowledge of the pathology of optic neuritis is unsatisfactory and that neither of the theories, clever and enticing as they are, are able to withstand criticism or investigation The conclusions reached by Gowers[1] are rational and in accord with the present state of our knowledge He says "It is probable that optic neuritis is rarely due to a single factor, and that the most potent element is the descent of a process of tissue irritation, which when it reaches the papilla sets up a more intense inflammation, that in some cases this influence is alone effective, that in others it is aided by the distension of the sheath which hinders the escape of effete products, increases edema, or even conveys irritating material

"The distinction between optic neuritis and choked disc is one of degree and not of mechanism So far as optic neuritis has any single significance, it is that of an irritative process within the skull"

Dr. de Schweinitz—I have listened with interest to Dr Morrow's paper, and would urge the importance of placing upon record, in connection with careful ocular examination, all cases of intracranial lesion, especially tumors, in which the position of the disease had been substantiated by a necropsy

We all know that there are the so called "quiet regions" in the brain I had a case in my own practice, of large tumor of the right frontal lobe, without the presence of active symptoms until about thirty hours before death The tumor occupied the white matter of the right frontal lobe as far back as the bases of the first and second convolutions, and from the ventricular surface involved the head of the caudate nucleus, and by softening, the structures as far back as the thalamos, and yet was practically, if not entirely, quiescent Optic neuritis had been present for some time and was probably the only symptom of the brain tumor until thirty hours before death, when convulsions, hemiplegia and conjugate deviation of the head and eyes to the left side were noted These symptoms were the result of a fresh hemorrhagic lesion in the left crus and on the left optic thalamos

I would urge the importance of a careful examination of the field of vision in all cases, especially if operative interference upon the intracranial lesion is contemplated I have the report of a case of epilepsy, not Jacksonian in type, which has existed for two years, with no other symptom save the convulsive attacks and headaches The fields of vision were concentrically contracted Two years later double optic neuritis and left lateral hemianopsia were manifest On the strength of the late development, hemianopsia, Dr Wood diagnosticated a secondary lesion in the cuneus, thinking it probable that the original lesion, a tumor, was connected with the cerebellum, because this was the 'region of silence" nearest to the area which gave evidence of the disease by reason of the hemiopic defect in vision The patient was trephined by the late Dr Agnew, and a cystic tumor, or area of inflammatory degeneration, found within the cuneus beneath the gray matter The patient died, and at the autopsy a large tumor occupying the second and third temporal convolution of the right side and approaching the fourth convolution, was discovered, together with a patch of hemorrhagic softening in the cuneus and a line of softening running nearly the whole length of the center of the occipital lobe The field of vision in this case correctly located a lesion in the cuneus, although it gave no evidence of the tumor in the temporal lobe on the right side, which hence may be involved without the production of immediate direct symptoms This case, utilized to illustrate the importance of the field of vision in localizing intracranial lesions, has been fully reported, both from the neurological and the surgical aspect, by Drs Wood and White

---

[1] Lectures on the Diagnosis of Diseases of the Brain W R Gowers M D, F.R C P, 1885, p 164

Dr Morrow—In reply to Dr de Schweinitz's remarks regarding the field of vision, I will say that it was impossible to get any satisfactory tests of the field Such rough tests as were possible were of no value, and so were not reported

I believe it to be highly important to impress upon the general practitioner the necessity of early and frequent examinations in cases of suspected head trouble, as well as in those cases where the diagnosis is clear, for the reason that positive evidence can often be obtained by the ophthalmoscope and perimeter, both as to the condition and location, that would escape other means

---

PURULENT OPHTHALMIA FROM THE STANDPOINT OF ITS SPECIFIC MICROBIC CAUSE,

WITH A PLEA FOR A MORE ENERGETIC, RATIONAL, ABORTIVE TREATMENT WHERE POSSIBLE

Read before the Section on Ophthalmology, at the Forty fourth Annual Meeting of the American Medical Association at Milwaukee

BY ALFRED HINDE, M D

SENIOR SURGEON EYE AND EAR DEPARTMENT, CENTRAL FREE DISPENSARY OPHTHALMOLOGIST TO THE NEUROLOGICAL CLINIC AND ASSISTANT TO THE CHAIR OF OPHTHALMOLOGY IN RUSH MEDICAL COLLEGE, CHICAGO, ILL

(*Concluded from page 564*)

Mauriac[37] decides that "the abortive treatment is indicated and has some chances of succeeding in acute gonorrhea only during the first hours of its outset" Diday[38] believes "That in the early stage every gonorrhea can be aborted," and "that the abortive treatment is neither locally nor constitutionally dangerous" Two methods may be followed a strong solution may be used for a short time in the urethra or a weaker solution may be left in contact for a longer time A 5 per cent solution of nitrate of silver is allowed to remain in the urethra from forty to ninety seconds, according to the pain produced A free discharge occurs after two days, and as a result of the burning may continue for four days and then gradually ceases in a few days more The abortive treatment is considered worthy of trial in view of the serious complications at times following a gonorrhea *If possible complications govern the use of abortive treatment of an urethral gonorrhea how much more urgent is this plan in a similar inflammation of the conjunctiva, because of their infinitely greater frequency and more deplorable results to the eyesight of these cases* According to Horner[39] the blind in different countries owe their loss of eyesight to this disease in from 20 to 79 per cent

In the newborn eye, Credé[41] of Leipsic, recommended the instillation of one drop of a 2 per cent solution of nitrate of silver and had the satisfaction of noting a reduction of purulent attacks from 7 5 to 0 5 per cent In the lying in hospital of Halle,[42] under the same treatment these cases fell numerically from 12 to 3 per cent *The mechanical*[43] *removal or the destruction* of *the gonococcus is the therapeutical indication in all these cases Remove the discharge and the loosened epithelia by watery solvent and brush, using at the same time and in the meantime an innocuous solution of the most powerful microbicide we possess* The personal element in the treatment of all diseased conditions enters largely, and the followers of a plan are not always as successful as the originator On this account, though all agree upon the same remedy, a few still advocate its use in strong solutions most carefully applied, for direct destructive effect, whereas, a more numerous company nowadays use nitrate of silver in weak solutions more freely and without injurious risk and with equally good results *Without known exception, it is decided that the remedy should only be used after suppuration has commenced*

Such a conclusion I most forcibly condemn as inaccurate and unscientific, and cite as my authorities the pathological facts of this paper, and those of my own clinical experience For years past I have looked upon all forms of conjunctivitis as closely associated with mycotic processes, and have treated them on anti bacillary lines, and invariably their severity and duration have been most favorably modified thereby If one microbe can produce a colony, and the latter only results in that wonderful process of attraction of leucocytes from blood vessel to mucous surface, and which we designate suppuration, where is the wisdom of waiting microbic multiplication with its resultant pus before applying our anti-bacterial methods *Here, without bacteria no pus* is sound antiseptic teaching, and if we destroy, or remove them from the conjunctival surface, where recently implanted, or few in number, we will avoid the appearance of suppuration and escape entirely the so called acute stage of the cases under consideration

Under any circumstances ample irrigation with thorough brushing of the conjunctival surface for the mechanical removal of secretion and microbes fills the indication For the purpose of removing microbes from an infected instrument, H Knapp[44] in 1886 found that irrigation with running water was insufficient, but by rubbing the blade with his fingers at the same time as washing and afterwards polishing with a towel he succeeded in sterilizing it Gayet[45] of Lyons, after carefully disinfecting the conjunctival sacs of his cataract patients still found that microbes remained in 75 per cent of them on making cultivation experiments Hence simple water, or solutions of antiseptics, with irrigation of the conjunctiva alone, are insufficient to insure thorough cleansing, and Knapp's rubbing of the instrument finds its parallel in a thorough brushing of the conjunctiva This method, however, did not suggest itself to me in this way, but was thought of as an ordinary common sense procedure If brushing will remove germs from a dermal surface why not also from a mucous membrane?

A fountain syringe and light pressure was suggested years ago by Dr C S Bull[46] A mucous solvent in the shape of bicarbonate of sodium, will be a good addition to simple sterilized water, and again it is indicated because the gonococcus grows best in an acid medium, and Dr M A Castillan[47] called attention to this fact and recommended its use in gonorrheal cases in solutions of 8 to 10 per cent He claimed that in old cases in which other remedies had failed the alkaline medication "led to rapid and complete recovery" In a later communication[48] he claims to have had excellent results in acute gonorrhea from the use of a 1 per cent solution A watery solution of boric acid can be used ad libitum, though we can not say this of solutions of corrosive sublimate, for Dr Friedheim[49] of Leipsic, working in Prof Neisser's clinic, has called attention to the fact that "perchlorid of mercury even in solutions of 1 to 20,000 causes pain and the anti-bacillary action is not great" in gonorrheal cases The conjunctiva, however, is not as sensitive as the urethra to this remedy, idiosyncrasy being excluded

Freidheim had an unusual advantage of observation, in 1,200 cases of gonorrhea, difficult of cure by the ordinary plans, and in the laboratory of discovery of the gonococcus, his investigations were carried out on anti-bacillary lines, and his conclusions are worthy of our attention in so far as we can apply them to the treatment of the conjunctival inflammation He tried to find out the best remedy that on local application would most completely *kill the gonococcus, lessen the inflammation, and promote epithelial desquamation* The best[50] results were obtained from a solution of nitrate of silver varying in strength from 1 to 4000 (gr $\frac{1}{8}$ to ℥i) to 1 to 2000 (gr $\frac{1}{4}$ to ℥i) Injections of the amount of 300 minims and retained for three minutes, were made three to six times daily, which were followed by increased and more purulent discharge "But in about four days the secretion diminishes, becomes thin and contains a quantity of epithelium The gonococci also diminish in a remarkable manner and after a few days disappear altogether When this has taken place the number of injections of nitrate of silver is reduced to two and afterward to one daily, and other injections such as boric acid, or some preparation of zinc (or tannic acid) are used as well But in spite of the almost total disappearance of the discharge the one daily injection of nitrate of silver is to be kept up for many weeks" Where nitrate of silver is not so well borne even in weaker solutions than those mentioned, a certain amount of success was gained by substituting solutions of "salicylate of mercury 1 in 270, with sodium chlorid, which completely destroys the cocci without much concomitant irritation" Other local remedies are referred to only to condemn, because of their uselessness as anti-microbics in permissible strength without producing undue pain and inflammatory reaction "In the very rare cases in which no antibacterial injection could be tolerated internal remedies were resorted to" *The best preventive of complications was found in the use of nitrate of silver injections* Neisser himself, at the recent meeting already referred to, when considering treatment, says that medicines should only be used which "*a*, destroy gonococci, *b*, increase the inflammation as little as possible, *c*, have no injurious action upon the mucous membrane, such as solutions of nitrate of silver 1 to 1-4000 to 1 to 1-2000, ammonia sulpho ichthyolate 1 to 100, sublimate 1 to 30000 to 1 to 20000" Thus science teaches what empiricism has long known by clinical experience, that of all remedies nitrate[51] of silver is the one *par excellence* for specific catarrhal inflammation of mucous membranes Our therapeutics have scarcely advanced in equal ratio with our recent bacteriological progression, yet the foregoing observations are sufficiently exact to show us that *weak solutions of this favorite remedy are amply sufficient to destroy the gonococcus without endangering any of the ocular tissues, and without causing undue pain and inflammatory reaction*

With the foregoing data as a guide I have long treated my conjunctival catarrhs with such satisfactory and rapid recoveries that now I care not whether they are specific or simple in character provided they are seen before complications of the eyeball impend, or have already occurred, provided also that my patient, or friends will intelligently favor and follow the treatment prescribed

When seen during the incubative stage I regard with especial probability of a specific origin all cases of rapidly increasing conjunctivitis in the newborn in females of every age and condition, in right eyes in right-handed, and in left eyes in left-handed adults

If suppuration has already ensued, or, in adults, if inquiry elicits the information of a gonorrheal focus previous to the appearance of the eye inflammation, the diagnosis is without difficulty

In all these cases free irrigation of the conjunctival sac, with thorough brushing of the tarsal portions and the retrotarsal folds is at once resorted to, generally without, but occasionally preceded by the use of a solution of cocain It is largely a matter of choice, in my opinion, whether you use sterilized water, solutions of bicarbonate of sodium, or boracic acid, or the weaker solutions of bichlorid of mercury The freshly made solutions of nitrate of silver of 1 to 4000 to 1 to 2000 appear to be of added advantage, and latterly I have, with increased satisfaction, *brushed into the affected membrane in the absence of ocular ulceration, a limited amount of a 2 per cent solution of nitrate of silver, washing off all excess after the brushing is ended* For a brush I cut off, evenly, half the length of fur of an ordinary camel's hair pencil, and find that the remaining stub is sufficiently firm for the purpose required *The brushing is continued until the parts are thoroughly clean and free from all secretion* Where cocain is not used, some pain is complained of, and continues for a time after each treatment This can be prevented by the use of cocain before and during this short period of irritation The ice cold applications of sterilized water, or weak antiseptic solutions on sterilized cotton, that are always applied in the foregoing lid and fornix inflammations, and used continuously between treatments and instillations, very quickly control any reaction due to the brush, and patients rarely complain of the method of treatment so great and rapid is the relief they experience from the severe eye symptoms of which they at first complained In private practice daily brushings are carried out, but in dispensary cases where this is impossible it was found that when applied every second day the diseased process was rapidly controlled

After two to four such thorough brushings the case is completely changed from a severe acute to a slight chronic inflammation with a corresponding decrease in the number of pus cells of the discharge Further require ments are simple removal of the exudations and two or three applications, once in twenty-four to forty eight hours, of a 1 to 2 per cent solution of nitrate of silver, kept up until the reduced succulency of the mucous membrane and the decreased discharge call for the transient use of the usual astringent solutions

If the foregoing method is adopted early enough and done thoroughly, complications never occur, and the duration of the infection is halved

In those further advanced cases where ædematous, thickened, and inflamed lid tissues prevent eversion of the upper lid, irrigation of the eye is as thoroughly accomplished as is possible, and where the cornea is intact, free use of two or three drops of a 2 per cent solution of nitrate of silver, instilled into the conjunctival sac and the lids lifted from the ball so as to permit the remedy to reach the ultimate confines of the fornices, is the chosen plan of treatment After waiting a few moments the eye is again flushed with simple diluent, and ice cold applications, and half hourly antiseptic instillations applied between daily office treatments

The lid swelling is thus rapidly reduced so that turning can be accomplished in one to two days, and the described brushings resorted to In those cases, when first seen, where complications of the eyeball impend, from lid-pressure causes, free canthotomy is done, because of its being the lesser of two evils The part that the ocular conjunctiva plays in these specific inflammations appears to be different in its resulting exudate from that of the palpebral portion and that of the retrotarsal folds The exudative inflammation of the latter is peculiar in the fact that its cellular elements are so numerous, whereas the chemotic exudation of the ocular, or scleral conjunctiva consists largely of fibrin-forming elements with some serum and few emigrating leucocytes

A thorough believer in the bacterial pathology of to-day, and *recognizing the character of the exudate into the scleral conjunctiva in the chemosis of these cases, I consider as worse than useless, for the purposes of pressure relief of a threatened cornea, the scarification of this portion of the conjunctiva* Knowing that, because of its connecting tear passages and on account of the presence of the ubiquitous pus microbe, it is practically impossible to insure aseptic operation of the conjunctiva under the best possible conditions of freedom from inflammation, as Fick,[52] in forty-nine perfectly normal conjunctival sacs, found only 12 per cent without bacteria, and thirty-six others, affected with slight catarrh, contained them, knowing that an army of microbes, in these purulent cases, is only waiting a doorway of entrance, that fortunately the compact stratified epithelium of the scleral conjunctiva and cornea prevents, so that they can readily attack and overcome the tissues with greatly lessened physiological resistance on account of their impaired vitality,—how then can we expect to aid the nutrition by wounding without removing the fibrino plastic exudate, and simultaneously opening up the lymph channels of the conjunctiva and subconjunctival spaces, these communicating with the same channels of Tenon's capsule, and those of the latter with similar lymph vessels within the sub choroidal[53] space of the eyeball, the pus microbes thus finding a ready made entrance with a possibility of terminating the case in the form of a suppurative choroiditis and loss of the eye This exudate may temporarily block the entrance way of the pyogenic microbes, but it is also the choicest soil for their growth and multiplication *For these reasons incision of ocular tissues for therapeutic purposes ought only to be a dernier ressort in infective inflammations of the conjunctiva Moreover, in all purulent cases where early, effective, rational treatment is carried out experience has shown that it is never necessary*

In the intervals between the personal treatments of these cases half hourly to hourly instillations of solutions of boric acid 2 per cent to 4 per cent, solutions of sublimate up to 1 to 5000, and fresh solutions of the nitrate of silver 1 to 4000 to 1 to 2000 have been used for home treatment Of the above solutions I prefer those of nitrate of silver, and use them in all cases where reactionary irritation is slight or absent and the cornea intact Many cases are greatly benefited by their use three or four times daily, the milder solutions being used in the meantime

Low temperature of the lids checks the multiplication of the microbes and continuous ice-cold applications soon reduce the swelling, pain, and increased temperature of the ptomaine-poisoned parts These are used as long as the acute inflammatory stage continues, and are afterwards directed subsequently to each caustic treatment and kept up until the reactionary irritation has disappeared

If when the case first appears there is ulceration and infection of the cornea sublimate solutions are chosen for irrigants, and, after cocainizing the eye, a 1 to 500 solution, on a cotton-tipped probe, is accurately and thoroughly applied to the ulcerated surface once daily, holding the application against the cornea for five to fifteen minutes The sublimate is five times[54] stronger than carbolic acid as an antibacterial agent and the appearance of the eye after its use, as above, is free from that unsightly whiteness that carbolic acid, in its 95 per cent solution, produces All excess of solution is avoided and the eye is afterward irrigated Where the cornea alone is involved, myotics are chosen as additional remedies, not on account of their mycotic action, but because, after a preliminary transient increase, they produce a decrease of the intra ocular tension by contracting the blood vessels, thus decreasing serous exudation In this way they sustain somewhat, if they do not actually increase the nutrition of the inflamed and softened corneal tissues (Ad[55] Weber), by limiting pressure from behind A mydriatic is the remedy where iritis or cyclitis impends, or has occurred, and in such cases only, because, after a preliminary reduction of tension, the intra ocular fluids are increased by it, resulting in increased intra ocular tension and added pressure from behind upon the inflamed cornea that will probably produce a staphyloma, and perforation of the latter On this account a supportive compress bandage over the affected eye should in all these complicated cases be worn during the intervals of treatment Paracentesis of the anterior chamber through the bulging cornea is never performed by me until perforation is assured, or positive, progressive, intra-ocular infection has supervened—for the reasons already given Again, repeated[56] experiments and clinical observation have shown that the eyeball, like other parts, can take care of without injury, and overcome or absorb, a certain proportion of infective bacteria without loss of the organ Once more a[5] hypopyon is frequently of non-microbic origin and its substance free from bacteria, and it is readily absorbed without damage to the eye It is therefore in those cases only where the infection overcomes all resistance, either from the number or virulency of its microbes, that section is called for, and in these cases even, it can scarcely do more than relieve the tension pains of a panophthalmitic condition

After the onset of ocular complications hot applications are used instead of cold ones, because they are more anodyne and comforting and less likely to further impair the decreased vitality of the tissues of the eyeball I almost invariably advise them as hot as can be borne and applied with sufficient frequency and continuity to control all pain They are used until reparative processes are well established The antiphlogistic and supportive eye bandage is retained until the repaired cornea is again unyielding, as is also the myotic, unless contra indicated as above

In one-eye cases the fellow eye is, where feasible, protected from the possibilities of infection by the usual eye shields

Since instituting the foregoing treatment in my practice the lessened fear of cases of purulent ophthalmia has been conducive to increased personal comfort Under it and when seen early the prognosis of simple and specific catarrh of the conjunctiva is practically the same Where the treatment is faithfully carried out complications do not occur The duration is greatly reduced Where complications already exist, the only eyes that are lost are the ones, when seen, involved in a virulent, progressive and unencompassable ocular infection in which all therapeutics are without avail The plan of procedure is but the compilation and application of facts gathered from numerous sources Whatever originality appears has been born of careful observation and clinical experience, and with the sole desire to rationalize our treatment and enhance the value of our methods in the management of these often desperate cases With full confidence I present this treatment for the consideration of those present, and feel assured that on its lines, faithfully followed, gonorrheal ophthalmia will fail to produce corneal complications in the usual three fourths of the afflicted eyes and will equally fail to make blind the 40 per cent as found by Klein[18]

CONCLUSIONS

1 That all cases of purulent conjunctivitis are of microbic origin and due to Neisser's gonococcus

2 That all cases originate from a gonorrheal focus, by devious paths, often, but not always traceable

3 That those parts of the conjunctival sac having a cylindrical, or a modified cylindrical epithelium, viz the palpebral portions and that of the fornices, are the seats of election of the micro-organism

4 That the location of the gonococcus on the mucous membrane is at first *super*-epithelial, then *inter*-epithelial, and still later *sub*-epithelial and all combined

5 That its special habitat is within the pus cell, yet it is also *extra*-cellular, as well as *intra*-epithelial

6 That the associated inflammation of the adjacent lid-tissues is due to the lymphatic absorption of the ptomaines of the microbe

7 That the compact stratified epithelial layer of the scleral conjunctiva and cornea is very resistant to the attack of the gonococcus

8 That ocular complications are due to pressure necrosis, producing an *infection atrium* through which the streptococcus and may be the staphylococcus find ready entrance to tissues with greatly impaired physiological resistance, and often rapidly destroy them—resulting in perforation of the cornea, intra ocular infection and loss of the eye This is a secondary infection

9 That the therapeutical indication is the mechanical removal or destruction of the gonococcus, with its ptomaine, and that if this is done early and thoroughly in the weeping stage, the period of acute inflammation will be cut short and the ocular complications avoided

10 That it is well in the incubative stage, even without positive evidence of a gonorrheal origin, to regard with suspicion all cases of severe monocular catarrh, and especially so in the female, irrespective of age or condition, and to treat them as if due to the gonococcus

11 That the mechanical removal of the discharges and the loosened epithelia and therewith the microbe and its ptomaine, *by thorough brushing of the palpebral conjunctiva and that of the fornices and* ample flushing of the conjunctival sac with simple diluents or weak microbicide solutions fulfills the etiological indication, and is non-injurious in all severe cases of *simple* catarrhal conjunctivitis

12 That of all local remedies nitrate of silver is the most potent and, at the same time, least irritating microbicide we possess It prevents complications, and can be used in sufficient strength to destroy the gonococci without risk of injury to *intact* ocular tissues, and that solutions of greater strength than 2 per cent are unnecessary

13 That in cases, when first seen, where complications already exist, brushing of the palpebro-fornix conjunctiva should be resorted to with thorough frequent irrigation of the conjunctival sac,—preferably with sublimate solutions up to 1 to 5,000 If undue lid-pressure exists *free* canthotomy is advisable, but scarification of the sero-fibrino-plastic chemosis of the scleral conjunctiva does not relieve exudative pressure on the ocular tissues, and it opens the doorway for secondary infection with pus microbes and is a dangerous proceeding

14 Where the cornea alone is inflamed, the added guarded daily use of a bichlorid solution 1-500 to the infected area is the best treatment, together with myotics, not on account of the latter's mycotic action but because, after a preliminary increase, they reduce intra ocular tension by contracting the blood vessels and diminishing serous exudation, and thereby they improve the nutrition of the ulcerated, softened corneal tissues *Paracentesis* of the anterior chamber, through the bottom of the ulcer, *is called for only in those cases where perforation impends, or where positive, progressive intra ocular infection exists*

15 The use of a mydriatic is best limited to those complicated cases where the uveal tissues are threatened, or inflamed, because, after a preliminary reduction, it increases intra-ocular tension by impeding the outflow of fluids from the eyeball, thus resulting in increased posterior pressure on the softened cornea,—impairing nutrition and aiding bulging

15 A supportive compress bandage is antiphlogis-

tic and of great use in preventing staphylomatous results in complicated corneæ, and its use ought to be continued until the healed cornea is again unyielding

17 Ice-cold applications check microbic multiplication, and ought to be used *assiduously* to the end of the acute stage, or until ocular complications ensue After the latter occur, applications as hot as can be borne are more comfortable and more conducive to the improvement of the nutrition of the impaired ocular tissues

18 As a prophylactic in monocular cases, the other eye ought to be sealed against infection, and the risks to others, from these cases, thoroughly advertised

19 The treatment of the initial focus of infection, where ascertainable in the affected subject, must be rigidly carried out on the same lines, and simultaneously with the conjunctival inflammation

ARE AMERICAN WOMEN PHYSICALLY DEGENERATED?

BY EDMUND ANDREWS, M D, LL D

PROFESSOR OF CLINICAL SURGERY CHICAGO

Some wild errors are afloat on the subject of woman's supposed degeneration In the October number of the *North American Review* Dr Cyrus Edson, Commissioner of Health for New York, gives a horrible picture of American feminine "deterioration "

He says that ' there is at the present moment in this country a condition existing among the women which is the cause of the greatest alarm " It begins, in his opinion, in the schools, where by ambition and by rewards for success and disgraces for failure, growing girls are goaded to a disastrous amount of mental strain and over-brain work "Thus stimulated they drive their brains and do the work" until their physical powers are wrecked, and in an "enormous number of cases the women have broken down as the result of a lack of stamina sufficient to meet the physical strain of child-bearing " Again he says "An increasingly large proportion of the women of the American race are unable to perform their functions as mothers " "We seem to be able to bring the women up to a certain point in mental development, and then they cease to be able to be mothers " And again he says it is a "fact that an enormous and increasing number of our women are so exhausted physically" (by over study) "before marriage that the birth of one child, or at most of two children, leaves them physical wrecks "

Again Edson says "Let me briefly state facts as they are An American girl, educated as it is our pride to educate her, marries the man of her choice amid the warm good wishes of all her friends She is clever, bright, beautiful One, or at most two children are born, and if we meet her we scarcely recognize her She looks dragged and worn, she is fretful and peevish, she has become a burden to her husband worse than all, because it is the cause of all, she is a confirmed invalid "

Now this does not convey a correct impression The Doctor, if he does not quite say it, leaves the average reader to infer that an "enormous number" constituting a "large proportion" of the American women become "physical wrecks" and "confirmed invalids" after bearing "one, or at most two children "

Myself, and three friends while talking over these gloomy assertions, determined to "sample" the community, and see how many of the women known to us had become "physical wrecks" after bearing "one or at most two children " Each of us have an extensive acquaintance, not only in and around Chicago, but among families now located all the way from the Atlantic to the Pacific ocean With pencil and paper we jotted down all the families whose condition we knew, mostly of New England, New York, Pennsylvania and Ohio origin In short, they were nearly all purely American in blood We took them all impartially, sick or well, without selecting or rejecting on account of health

By a very moderate amount of conference together, supplemented by a little inquiry, we readily made a list of 163 families in which the mothers had borne from one to thirteen children Classifying them according to their health we found the facts as follows

1 Fifty-two mothers had borne from one to thirteen children each, and came out with robust, magnificent health, better than that of average men or women Three of these had borne respectively eleven, twelve, and thirteen children, and came through in brilliant health In fact the women with large families seemed on the average to come out the best

2 Ninety-five mothers, who had borne from one to eight children each came out in good, average, nice health, without being, however, so robust as the first class

3 Eleven were delicate, but not great sufferers

4 Five were confirmed invalids

No class of men or women is totally exempt from sundry ills, and occasional deaths but we could not find a single one physically wrecked by childbirth in a constitution exhausted by over study We found several who had been delicate before marriage, and became robust after bearing children

When deaths occurred among these generally healthy women, it was from the occurrence of mechanical injuries, typhoid fever, consumption, cancer, pneumonia etc, and not from previously exhausted systems "broken down under the physical strain of child-bearing "

These women, had already at the *time of our* enumeration produced about 545 children which averages over three and a third to each mother, and as many of them are still young, and nearly all healthy, they will yet add many more to the list of offspring

GOLD IN THERAPY

Read at the Meeting of the Mississippi Valley Medical Association, Oct 4, 1893

BY E A WOOD, M D
PITTSBURG, PA

Gold is one of the old remedies which has been crowded to the wall by the more brilliant achievements of modern pharmacy It is safe to say that one-half the medical profession never prescribe gold, the large body of the other half use it occasionally, while a very small minority employ it constantly in the class of cases in which it is best suited

Gold, practically, to the main body of the profession, is a new remedy From the company it has fallen in with of late, gold is open to suspicion, and whether it is a partner in the "Keeley Cure" or not, many will be prejudiced against it It would seem timely and just to drag the old drug from its dusty closet, and tear it away from its bad company that we may learn what standing it really deserves in therapeutics

What, then, is the pathological condition in which gold is especially indicated as a curative agent? Let us answer this question with as much precision as possible If gold has a place in therapy it must fill a special place, for it, like all other drugs, is no universal panacea What is its place?

What say authorities in reply to this question? In view of its great age, it is astonishing how meager the literature It is still more astonishing that until within a very recent period we had practically but one preparation of gold—the chlorid of gold and sodium That preparation to-day is the one given, and by it the standard of gold is rated as a curative agent Gold is as old a remedy as mercury, and yet gold to-day is almost unplaced in therapeutics The compounds of mercury are legion, its history voluminous, and its therapy accurately known and established We know more perhaps about mercury than about any other drug, we know less of gold than of most drugs

Authorities agree in declaring that the chlorid of gold and sodium is an alterative, behaving very like mercuric chlorid No author gives gold a very wide range in therapy, no one attempts to name the exact pathological condition in which it is best indicated and most efficient, and nearly all who have written on gold in therapy, whether designedly or not, succeed in "damning it with faint praise" Syphilis is one of the diseases in which it is commended, some say in the secondary lesions, others that it is best suited in the tertiary form The praise given gold in syphilis is not high, certainly not so loud as the praise given mercury It is said to be aphrodisiac and emmenagogue Tabes dorsalis, cirrhosis of liver, lungs and kidneys are said to be cured by gold Some praise it in diseases of the glandular system, especially in disease of the glands of the stomach and intestines, increasing appetite, and promoting secretion, digestion and nutrition It is said to give force to brain action, to give courage to the despondent, hope to the hypochondriac and content to the melancholic All speak of it as affecting the gums without salivation, producing an eruption of the skin and gold fever The latter I have never seen

That is the sum and substance of what therapeuticians say of the chlorid of gold and sodium But there are three questions which are still unanswered. First, is the chlorid of gold and sodium more efficient in the lesions named than any other drug? Second, is gold in therapy limited to the one double salt? Third, what is the special pathological condition in which gold is most efficient as a curative agent?

Leaving out the first question for the present, I shall undertake to answer the other two as observation and experience have taught me

My more immediate purpose is to direct your attention to some preparations of gold other than the chlorid of gold and sodium, samples of which are before you

The first preparation I shall notice, and the one with which I am best acquainted, through prescribing it for the past seven months in the place of the double salt, is the liquor auri et arseni bromidi. The successful combining of gold with bromin, mercury, arsenic and other metals, is owing to the indefatigable labors of Dr W F Barclay of Pittsburg, who persevered in face of the decree of some chemist that such compounds are impossible There stands the liquid bromid of gold and arsenic There stands the liquor of gold and mercuric bromid Here are other preparations of gold combined with other metals As there is no filtering employed in the manufacturing of these liquors, every atom of the metals must be present The two liquors are, as you see, beautifully red and transparent, elegant as the garnet fluids in the show bottles of a druggist's window I am not sure that it will not fade under exposure to light, but I know that after months standing not a shadow of sediment mars its complete transparency It is almost tasteless The dose—10 drops—contains one thirty-second grain of gold and one sixteenth grain of bromid of arsenic The mercuric bromid of gold contains one thirty-second grain each of gold and bromid of mercury to 10 drops, which is the dose Each preparation is pleasant to take, is more readily absorbed than the chlorid of gold and sodium and, in my experience, more assimilable and active than the double salt Of course the gold is modified and its action intensified by the combination with other metals It is probable that gold will readily combine with all other metals used in therapeutics

The class of diseases in which I have found gold to be peculiarly efficient, and in which it seems to be especially curative above all other drugs, is that class in which *sclerosis* is the chief factor In naming scleroses as a class, I am perhaps taking undue liberty with the nomenclature of the pathologist, since the term sclerosis is generally understood to mean induration of the tissues of the brain and spinal cord Literally, it is proper to apply the term sclerosis to any organ or tissue in which induration is the factor When we marshal such pathological conditions into a class, we shall find that sclerosis has a wider and, it seems to me, a more significant meaning than hitherto attached to the word and the lesions it names It would seem as though we have reduced therapeutics to an exact science when, instead of a name, we establish an exact pathological condition, with the remedy most efficient in removing that condition That is the exactitude we have in gold as a special curative agent in all forms of sclerosis

Cirrhosis of the liver, interstitial nephritis, atheroma and its associate, calcareous degeneration of the arteries The circumscribed induration following embolism or bloodclot in the brain tissue, senility and its train of decrepitudes—for what is old age but a general sclerosis—all belong to the class I have named Cirrhosis of the lungs, certain forms of consumption—fibroid consumption, miliary tuberculosis, and especially that form of consumption in which masses of lymph become organized in the lymphatics of the lungs as we see the process in the glands of the neck and called adenitis Without naming all the lesions that may be classified under the head sclerosis I will state, as my belief, founded on an experience of twenty years, that gold is far more efficient in them all than any other drug I know of I desire to say in addition that the liquid preparations of gold as combined with bromin, arsenic, iodin and mercury are as much superior to the chlorid of gold and sodium as is quinin over the crude Peruvian bark

In addition to its efficiency in the sclerosis it would seem as though gold, at least the liquor auri et arseni bromidi, exercises a power as a tonic and nutrient to the nervous system, especially to the nervous systems of those who have advanced to fifty and beyond May it not be that in cases of neurotic diseases of the aged there is a sclerosis? Certain it is that gold is not so efficacious in functional nervous ailments of the young It is just to remember, too, that the association of gold with bromin and arsenic may have very much to do with its curative powers But for all that, gold and its preparations is the medicine for those in middle life and in old age It stimulates the brain, incites a flow of spirits, gives sleep to the sleepless, courage to the despondent and intensifies sexual desire and power Gold should maintain physical vigor and prolong life even if taken when there is no disease except the inherited tendency to decay before reaching the Bible limit of life

In presenting a few cases taken from my clinical day-book I beg leave to remark that I appreciate incredulity, and with that thought before me I am guarded in my statements, feeling that a modest conservatism will be tolerated by you, whereas you would smile at and ignore the vivid praises of the enthusiast

E H, aged 57, roofer, temperate with good heredity and void of syphilis or any cachexia Had complained of what he was told was rheumatism of the knee joints since February, 1892 Visits to seashore, and Mt Clemens, together with medication from various physicians, did not arrest the disease which grew steadily worse On the 14th of May last I saw him with Dr Barclay His knees were swollen, stiff and painful, preventing rest or sleep He preferred to have his legs amputated rather than endure his agony We diagnosed the case as *Arthritis Deformans*, and put him on the liquor auri et arseni bromidi In six weeks time he pronounced himself cured, the pain and stiffness were gone and the swelling was very much reduced He still remains well up to date

R E M, aged 45 Heredity good Having treated him for a year for locomotor ataxia, by suspension, ergot and other usual remedies, I placed him on the liquor of gold last July He sleeps better, appetite improved, not so despondent, the girdle pain and the pain in feet is very much abated, but there is no improvement in the coordination He is still taking the gold

C T, periodical dramdrinker Took the gold two weeks, at the end of which time there were ulcers in the mouth and the teeth in lower jaw were loosened

M Mc, aged 52 Heredity good Very fond of women and noted for his sexual powers and endurance Had suffered for eighteen months with neuralgia of the left trifacial nerve Had tried various forms of treatment, among others that of having the sound teeth extracted from the left lower jaw, but without relief Speaking was painful, mastication impossible and swallowing of liquids agonizing He was haggard with pain and loss of sleep In spite of his protest, I treated him for syphilis by giving him mercury and the iodid of potassium He improved very considerably, but the pain persisted though to a slight degree, and grew worse on stopping the mercury In June last I put him on the mercuric bromid of gold, with rapid improvement, and he pronounced himself cured He still takes the gold occasionally

I have administered the bromid of gold and mercury in two cases of iritis with evident advantage

Two cases of fibroid consumption, with cavities, both the result of neglected pneumonitis, are astonishingly improving under the use of the bromid of gold and arsenic internally and the inhalations of papoid glycerol by the atomizer

One case of pneumonokoniosis, "grinders' consumption," had resisted treatment for four years, during which the patient lost in weight while cough and expectoration increased In July I put him on the bromid of gold and arsenic with papoid inhalations September 27, coughs a little on rising in the morning, expectoration no longer black Gained fifteen pounds in weight

One case of miliary tuberculosis in which the pulse was 130, temperature 101, respiration 30, is rapidly improving on the gold

Two cases of diabetes have improved under the use of gold, one of them so much so that he was accepted last August as a good risk by one of the foremost life insurance companies In both cases I gave codein at the beginning of the treatment, but left it off and continued with the gold

A case of adenitis, with enormous enlargement of left side of neck, is being rapidly cured by the bromid of gold and arsenic

Does gold ever fail to cure? Yes, if given in cases unsuited for it But in the scleroses, while it may fail, it will accomplish more cures than any other remedy

---

POINTS OF DISSIMILARITY BETWEEN US AND HOMEOPATHIC PHYSICIANS

An Address read before the Lancaster City and County Medical Society, July 5, 1893

BY J L ZIEGLER, A M, M D

PHILADELPHIA

Mr President and Gentlemen —The JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION for May 27, 1893, publishes the annual address of the President of the Philadelphia County Medical Society, read May 24, 1893, by Jno B Roberts, A M, M D, entitled "Points of Similarity Between Us and Homeopathic Physicians"

Dr Roberts believes "that the tests of qualification for membership (in the Philadelphia County Medical Society) should not be the college from which the applicant received his diploma, but an education enabling him to understand and appreciate the science of medicine, and an honest purpose to treat his patients by all means and methods which experience, investigation and research show to be serviceable"

Admitting the proposition to be true, then one who graduates from the Hahnemann Medical College and desires to become a member of the Philadelphia County Medical Society, would have to repudiate his college and the doctrines it inculcates, or practice a gross fraud upon the community and the society with which he desires to connect himself

He further endeavors to show our similarity because we both 'are law abiding citizens," that "we meet each other in drawing-room, mart or amusement hall, to find no difference in courtesy, refinement or large-hearted charity" All of which does not substantiate our similarity as physicians, but is mere sentimental exuberance

He regrets "that a marked similarity exists between the ignorant and half-educated graduates of all kinds of medical colleges" In these regrets we most heartily agree He continues to demonstrate our similarity by giving a list of textbooks recommended officially, to be used in the Hahnemann Medical College, of Philadelphia, and that they are the same as those used by our own schools, showing clearly that the college training of our students is very similar, but the Doctor forgets to give us the textbook of the institutes of medicine

The teaching of this branch by Prof Dudley includes the relationship existing between the methods employed by the physician and surgeon and the objects sought to be obtained, in other words, the principles which determine and direct all therapeutics, whether preventive, palliative curative or reparative The major part of the course will be devoted to instruction in the principles of Hahnemann's *Organon*—with the scientific arguments upon which homeopathists base their acceptance of the Law of Similars, and the facts and statistics by which its efficacy and superiority are demonstrated" (*Forty-fifth annual announcement of the Hahnemann Medical College for 1892–1893*)

What the principles of Hahnemann's *Organon* are will be noticed hereafter

Again the Doctor says "A very striking similarity between us and our homeopathic neighbors is the latitude of opinion exercised in the choice and administration of drugs Many thoughtless persons believe that we give only large doses, homeopaths only small ones, that we do not use powders or triturates, that they do not write prescriptions or administer alcohol or opium Nothing is easier than to show the fallacy of these statements"

As to the choice and administration of drugs, there is no doubt as to the fact that the homeopaths use the same drugs that we do But here the similarity ends They doubtless use many drugs that we do and some that we do not, but they use them in such infinitesimal doses that the mind can not appreciate even by comparison their minuteness

To illustrate, let me quote a portion of the *Organon* "To serve the purposes of homeopathy the spirit like medicinal powers of crude substances are developed to an unparalleled degree by means of a process which was never attempted before, and which causes medicines to penetrate the organism and thus become more efficacious and remedial" 'It is applicable even to those substances which in their crude state do not evince the least medicinal effect upon the human body Thus two drops of the fresh vegetable juice mixed with an equal proportion of alcohol, and diluted with 98 drops of alcohol, and potentiated by two successions of the hand—this is the first development of power (potency) The same process is then to be repeated with 29 successive vials, each vial to contain 99 drops of alcohol, filling three quarters of the vial, this second vial is then to be shaken twice, and so on to the thirtieth development, this is the potentiated decillionfold dilution, and the one to be commonly used" (*Hahnemann's Organon*, page 178)

Dr Garrett in his work on 'Myths in Medicine" calculates the quantity of alcohol required to reduce one drop of crude juice to the sixth potency to be 1,356,336 large hogsheads of 120 gallons each

Imagine for a moment the quantity of alcohol required to reduce the same to the thirtieth potency!

In reducing powdered substances (I should say increasing "the spirit-like medicinal power of crude substances"), sugar of milk is used instead of alcohol, and it may be safely said that since the days of Hahnemann and if homeopathy should exist one thousand years hereafter not enough sugar of milk could be manufactured to reduce one entire grain of a crude drug to the thirtieth potency But you say this is an exaggeration Let me explain the first potency is made by taking one grain of any drug and adding thereto 99 grains of sugar of milk and after a number of triturations and successions we have the first potency, one grain of which contains the 1-100 of a grain of the crude drug, the second potency is made by taking one grain of the first potency and adding thereto 99 grains of sugar of milk (rejecting the remainder), and after triturating and shaking we have the second potency, one grain of which will contain the 1-10000 of a grain of the crude drug—by repeating the process, always taking one grain of the last potency until the thirtieth potency is reached, which is the one Hahnemann recommends to be most frequently employed, although some enthusiastic homeopaths continue the process to the two and three hundredths potency Hahnemann says in a note on the preparation of fluid medicines that "desirous of employing a certain rule for the development of powers of fluid medicine, I have been led by manifold experiences and accurate observations to prefer two instead of repeated strokes of succussion for each vial, since the latter tended to potentiate the medicine too highly" (*Organon*, page 221)

I have made an accurate calculation of the quantity of sugar of milk required to reduce one grain of any crude drug to the sixth potency, and find that it would require 701,423 tons, and that the actual quantity of the crude drug contained in the thirtieth potency is represented by this fraction 1 10000000000000000000000000000000000000000000000000000000000, whatever it may represent, and I must confess that my arithmetical knowledge is too limited to give it a name, and that my mind is too dull to form a conception of its minuteness I must not forget the similarity of the mode of administration of drugs, as that is one of the points mentioned by Dr Roberts

Hahnemann says "Homeopathic remedies will act with the greatest certainty and efficiency, particularly by smelling or inhaling them in the form of vapor emanating continually from a dry pellet impregnated with a highly rarefied medicinal solution and contained in a vial" The homeopathic physician should apply the mouth of the vial first to one nostril of the patient and request him to inhale the air from the vial, and if the dose is to be somewhat stronger, the vial should also be applied to the other nostril, the patient inhaling more or less vigorously in proportion to the intended strength of the dose, whereupon the vial should be replaced well corked in the pocket case to prevent abuse

Hence the physician may dispense entirely with the services of an apothecary if he chooses to do so Globules (of which ten, twenty or one hundred weigh a grain,) moistened with the thirtieth potentiated dilution and then dried, retain their full strength undiminished for at least eighteen or twenty years, (as far as my experience reaches,) even if the vial had been opened a thousand times, provided however, it had been well protected from heat and sunlight" (*Organon* page 224)

How similar this is to our mode of administration needs no explanation—that such refined nonsense should be seriously considered in this nineteenth century is one of the anomalies of this erratic age But this is not all of homeopathy, it is only the smallest part of the fallacy Hahnemann denies the existence of a 'materia morbi," and attributes all diseases to "spirit-like force (autocratic) which he calls "dynamis" "In sickness this spirit-like self acting (automatic) vital force omnipresent in the organism is alone primarily deranged by the dynamic influence of some morbific agency inimical to life" "Hence disease (not subject to the manual skill of surgery) considered by allopathists as a *material thing hidden within but distinct from the living whole, (the organism and its vital force) is a nonentity, however subtle it is thought to be*"

It could have originated only in the minds of materialists, and has for a thousand years imparted to medical science manifold deplorable directions stamping it as an unwholesome instead of a healing art" (*Organon* page 68)

Before proceeding to show the fallacy of this doctrine of spirit-like vital force or dynamis I will again quote from Hahnemann's *Organon* (page 154, sec 204) "By placing in one class all protracted diseases, arising from unwholesome habits of living, together with countless drug diseases produced by the persistent and debilitating treatment often employed by old school physicians in trifling disorders, we shall find that all other chronic diseases without exception, are derived from the development of three chronic miasms, internal syphilis, internal sycosis but chiefly and in far greater proportion internal psora Each of these must have pervaded the entire organism, and penetrated all its parts before the primary representative local symptoms peculiar to each miasm (itch eruption of psora, chancre and bubo of syphilis, and condyloid excrescence of sycosis) makes its appearance for the prevention of inner disease When its local symptoms are suppressed the internal disease will be developed sooner or later, in obedience to the laws of nature It will be followed by endless misery in the form of innumerable chronic diseases which have been the scourge of the human race for thousands of years, and these would never have prevailed to such an extent, had physicians endeavored rationally and zealously to cure and eradicate each miasm by internal homeopathic treatment and well selected medicines, instead of tampering with their local symptoms by topical applications"

I believe the itch insect was not discovered when Hahnemann invented his system it has since been demonstrated to be a very lively "spirit like force or dynamis," a very inveterate sort of "nonentity," a 'materia morbi" come to plague the homeopathists—what a terrific scratching among the faithful! and then 'the typhoid bacillus, the comma bacillus of cholera, the pneumococcus, the gonococcus and a host of other cocci's that have come to disturb the equanimity of the spirit-like homeopathic afflatus but then these are only spirit like nonentities, a sort of miasm' so to speak, to be cured, eradicated and stamped out by' smelling a homeopathic pellet about as large as a mustard seed more or less, moistened with the thirtieth potency of some anti-psoric, anti-sycotic or anti-syphilitic as the case may be But seriously what of the law of similars, the great concentrated principle of homeopathy, the "similia similibus curantur," the one great law of the system? and here let me remind you that this is the principal feature which makes us to differ, and which Dr Roberts believes to be of so little importance that we could easily coalesce, join the same medical society, meet each other in consultation, and take each other by the professional hand as brothers pursuing the same noble calling

This dogma is based upon the supposition that there are three sources of disease depending upon the existence of three miasms (syphilis, sycosis, and the itch,) and that they are antagonistic, that is if a syphilitic disease and apsoric disease exist at the same time in the body, that one or the other will be held in abeyance in the body until the one that has the precedence shall have expended its force, when the other will manifest itself, but if they should be similar, that is both psoric or both syphilitic, then the stronger will eradicate or cure the weaker, and thus effect a spontaneous cure—hence Hahnemann inferred that drugs prepared and administered homeopathically that are capable of producing symptoms in the healthy body similar to the symptoms of the disease, do eradicate the actual disease He says "Consequently experience leads to the undeniable conclusion that the living human organism is far more disposed and inclined to be affected, and to have its feelings altered by medicinal powers than by other noxious agencies and contagious miasms, or to express the same in other words *Extraneous, noxious agencies possess a subordinate and often extremely conditional power, but drug potencies possess an absolute unconditional power* far superior to the former in *ability* to produce ill health (morbid discordancy) of the human body (*Organon*, page 76, Sec 33) Again

'The greater intensity of artificial disease produced by drugs, does not constitute the only condition of their ability to cure natural diseases In order to perform a cure, it is necessary that drugs should possess the power of producing in the human body an artificial disease, *most similar to that which is to be cured*, for it is by virtue of its similarity combined with greater intensity, that the drug disease is substituted for the natural disease, thus depriving the latter of its power to affect the vital force This is true to such an extent, that even nature herself is unable to cure an older disease through the accession of a new *dissimilar* affection, even of greater intensity, nor can the physician perform a cure by means of drugs *incapable of producing in the organism a diseased condition similar to that which is to be cured* (*Organon*, page 76, Sec 34)

"All these examples prove that neither the efforts of nature nor the physician have ever been able to extinguish or cure a disease by means of a dissimilar morbific potency, however powerful, but they prove that according to eternal and irrevocable laws of nature which were hitherto misinterpreted, cures are made to result *alone from morbific potency which is similar in symptom and somewhat superior in strength* (*Organon*, page 88, Sec 48) Again he says ' The true homeopathic method of cure is the only correct, the only direct and the only possible means to be employed by human skill, as surely as it is possible to draw but one straight line between two given points" (*Organon*, page 92, Sec 54)

This is a very strong and positive assertion, but how does Hahnemann know of this certainty, of the potency of drugs—he tells us that it is proved by actual experiment upon the healthy human body—not by appreciable doses but by highly attenuated potencies or dilutions This is the last great fallacy of the system, and is best explained in Hahnemann's own words He says "Medicines should, therefore, be distinguished from each other with scrupulous accuracy, and proved by pure and careful experiments with regard to their powers and true effects upon the healthy body For upon the accuracy of this test (proving) depend life and death, sickness and health of human beings The test should be so conducted as to result in the acquisition of accurate knowledge of drugs, as well as to avoid every mistake in using them in diseases, for the unerring selection of remedies is the only condition for the speedy and permanent return of health of body and soul, the highest gift bestowed on man" (*Organon*, page 125, Sec 120) Again "The most recent experiments have taught that crude medicinal substances, if taken by an experimenter for the purpose of ascertaining their peculiar effect, will not disclose the same wealth of latent powers as when they are taken in a highly attenuated state, potentiated by means of trituration and succussion Through this simple process the powers hidden and dormant, as it were, in the crude drugs, are developed and called into activity in an incredible degree In this way the medicinal powers, even of substances hitherto considered inert, are most effectually developed by administering to the experimenter daily from four to six of the finest pellets of the thirtieth potentiated attenuation of one of these substances, the pellets having been previously moistened with a little water, should be taken on an empty stomach for several days" (*Organon*, page 127, Sec 128)

The only answer to this attenuated absurdity would be to pass it over in silence, were it not that (in the latter part of this nineteenth century) a professor occupying the chair of the institutes of medicine devotes the major part of his time to prove the efficacy and superiority of the Hahnemann method of treatment, and that we are asked by the president of the Philadelphia County Medical Society to lay aside our manhood and unite in consultation with the disciples of this finely spun moonshine

Let us examine the doctrines in the abstract—doctrines upon which the whole superstructure of homeopathy is built

1 Disease is caused by a spirit-like force, a dynamis

2 All diseases (not subject to surgical skill) arise from three miasms, namely syphilis, sycosis and the itch

3 These three miasms are antagonistic

4 That drugs properly potentiated are capable of causing similar diseases in the healthy human body to a greater extent and are always more powerful than this dynamis

5 That this power is proved by the administration of drugs (properly potentiated) to the healthy body

6 That this power possessed by drugs is capable of removing disease, when given in attenuated doses, by causing a similar but more powerful drug disease

This is the whole system of homeopathy expressed in a few words But we may abridge this system still further into two propositions, viz 1, that disease is a spirit-like force and not a materia morbi 2, that drugs possess (when properly attenuated and potentized) the power or spirit-like force to produce a similar drug disease, but always more powerful, thereby expelling the actual disease—that is, one evil spirit expelling another evil spirit—Satan casting out Satan But the good Book tells us that a house divided against itself can not stand, but must fall As already stated, the discovery of the itch insect and the many demonstrations of the bacteriologist effectually refute the first proposition, and as the second depends upon the first—in fact, all the propositions are dependent upon the spirit like force, both as a cause and a cure of disease,—nothing remains of homeopathy but the name, no sensible person can believe such fatuous extravagances

But Dr Roberts says that "If the action of homeopathic medical societies, of homeopathic medical journals, and the spoken and written statements of homeopathic physicians are examined, it is evident that very many of those whom the public regard as homeopathists have comparatively little faith in the infinitesimal doses of Hahnemann or in the infallibility or universality of his law"

I am fully aware of this fact, but it only proves the fraudulent practices of the homeopathists

Their pretended adherence to the homeopathic system—calling themselves homeopaths and at the same time using our medicines in the same appreciable doses and attributing their cures to homeopathy, is a gross fraud upon the community

No one objects to their practicing the system pure and simple—they well know that homeopathy would not exist to day if they would practice it as laid down by Hahnemann, although they use his *Organon* as a textbook and teach its principles as superior in their efficacy Hahnemann despised such physicians, who practiced both systems He says "Who would honor this careless and pernicious class with the name of homeopathic physicians after the salutory art? May their just rewards await them, that if ever sick they may be cured after their own fashion" (*Organon*, page 207)

Hahnemann was sincere, he believed our system to be pernicious and homeopathy the only possible method of cure, he denounced our method as wrong in toto

Almost every page of the *Organon* has dire allusions to the effects of the old school practice, which he alleges produces an incurable drug disease, and he expresses his gratitude to an all-wise Creator who has allowed homeopathy to be discovered Now, his pretended followers almost worship Hahnemann They build colleges and call them after his name, they rear monuments and statues to his memory everywhere, they sing loud praises of his virtues, they make his great work, the *Organon*, their textbook, then they fill their medical cases with every variety of old school drugs, practice our system under the cloak of Hahnemann, and thus impose on a credulous public Language is inadequate to express my contempt for such procedure "I had rather be a dog and bay the moon than such a Roman"

The president of the Philadelphia County Medical Society pleads for their reception in our medical societies, excuses their practice of the *similia similibus curantur* and their silly dilutions as so small a matter that we should embrace them as brothers Methinks I see the ghost of Hahnemann smile at the humiliating picture Dr Roberts quotes from homeopathic journals and homeopathic writers to show our similarity He says "This rather lengthy series of quotations from homeopathic writers has been made to establish my point, that we and most of them are for all practical purposes similar and at one They, as well as we, are free to choose whatsoever is thought to be the proper remedy for a diseased condition and to give it in whatsoever dose is considered curative" If such be the case, and we do not doubt it, let them abandon the name of homeopathy, practice rational medicine and show fruits meet for repentance Let them cease to oppose legislation and to demand a separate board of medical examiners If they are sincere and so near similar to us that Dr Roberts can see no difference, if, after practicing their silly nonsense for nearly a century, and by every subterfuge endeavoring to convince a credulous public that their method of treatment is the only true and positive method of cure, they are now beginning to see its folly, let them come to us in a legitimate manner by acknowledging their error and cease to teach their dogma of *similia similibus curantur* to their students We are not under obligations to them, nor will we 'crook the pregnant hinges of the knee where thrift may follow fawning" The gist of this matter is a paving the way toward a revision of the Code of Ethics, so as to allow a few specialists and those who hunger after the almighty dollar in the way of consultation fees to consult with homeopaths without violating the Code It behooves the profession to watch these men and not let them touch the Code by way of revision It is good enough for all, and its provisions prevent no one from pursuing a gentlemanly, true and honorable course

THE DISSIMILARITY BETWEEN PHYSICIANS AND HOMEOPATHISTS

A REPLY TO THE PRESIDENTIAL ADDRESS OF DR JOHN B ROBERTS

Read before the Philadelphia Medical Society, Oct 11, 1893

BY SOLOMON SOLIS-COHEN, M D

PROFESSOR OF CLINICAL MEDICINE AND APPLIED THERAPEUTICS IN THE PHILADELPHIA POLICLINIC ONE OF THE PHYSICIANS TO THE PHILADELPHIA HOSPITAL

This communication is presented at the request of a number of members of this Society who desire a record to be made of their dissent from some of the views advanced by Dr Roberts in his paper entitled, "Points of Resemblance Between Us and Homeopathic Physicians" The subject matter having been discussed by me at length in a paper read before the Society some years ago,[1] I may be pardoned for confining myself on the present occasion to a brief review of a few of Dr Robert's "Points" and to the introduction of but one counter-point

I have read somewhere an apologue which, slightly modified to suit the present occasion, runs thus

In the country of the Houhnhyms, concerning which land, its inhabitants and their customs, an interesting and reliable account has been left by the late learned and ingenious Gulliver, there was at one time an agitation in favor of what was termed "liberalization of the Constitution" In furtherance of this movement there was presented to one of the scientific societies, by an eminent and thoroughbred stallion, a very able paper entitled, "Points of Resemblance Between Us and Jackmules"

With the great generosity and candor which were its author's characteristics, this paper, while admitting that all mules were not alike, and that the earlier breeds had been quite obnoxious, yet claimed that in recent times a great change had taken place, that, indeed, mules were becoming every day less mulish, and it counted in favor 'of the great body of mules at the present time," even down to the least fraction of an inch by which their ears had been shortened, and the last hair in the little bunch at the end of their tails, every point wherein they had never so slightly departed from the anatomy of the more lowly line of their parentage, and approached to the form and features of the noble line that they shared with the speaker Many of the younger Houhnhyms were moved by his eloquence to respond to the generous impulses of the advocate of fraternization, and it appeared as if his views might prevail At this juncture a veteran "stud" arose, and with great gravity and deliberation spoke about as follows

"My noble friend has shown most clearly and convincingly that many Jackmules have done their best to imitate Us Let me even admit for argument's sake that he has succeeded in establishing many points of similarity But he must grant me permission to call attention to one point of difference There never was a mule yet but he was sired by a jackass"

Dr Roberts pays a handsome and well-deserved tribute to the personal and social qualities of educated homeopathists I can cordially indorse all that he has said upon this topic The question of scientific or ethical truth, however, is an impersonal one, and should be so considered The fact that Washington was a slaveholder did not make slaveholding right, and neither the high character of Dr Roberts, nor that of many members of the homeopathic fraternity can make white black or black white, make straight that which is crooked, or make crooked that which is straight

The question before us is one of simple honesty, and to decide it needs neither learned citation of authorities nor casuistical subtleties Either the name, "homeopathist," means something or it means nothing If it is meaningless there can be no legitimate reason for retaining it If it has a meaning it means separation from and opposition to progressive medical science, it means an assertion of belief in a certain well-defined dogma opposed to reason and to experience, an assertion, moreover, made for effect not upon medical colleagues, but upon the lay and uninstructed public It is only right, then to hold those who make use of that name to all the implications of the voluntarily assumed designation

A professed homeopathist can no more sever himself from the history of his sect than a mule can sever himself from the lineage of his sire Without jackasses, no mules, without continual Hahnemannian fecundation in each generation, no homeopathy

I agree fully with Dr Roberts, that neither "a physician's political religious, or social beliefs and affiliations, nor his opinion that in 'similars' he sometimes finds a remedy of value, should disqualify him" from membership in this Society But who has ever urged that any of these things should be disqualifications? That one's possible 'opinion that in "similars' he sometimes finds a remedy of value" does not act as a disqualification, Dr Roberts himself shows in the further course of his paper, quoting, moreover, the language of the American Medical Association 'neither is there any article or clause of the Code of Ethics that interferes with the exercise of the most perfect liberty of individual opinion and practice'"

What Dr Roberts either fails to see, or refrains from commenting upon, is the fact that to hold the "opinion that in 'similars' one may sometimes find a remedy of value," is quite a different matter from labelling one's self "homeopathic" To believe that in electricity "one sometimes find a remedy of value," is not, therefore, to be an "electropathist," to use water as a therapeutic agent in suitable cases does not make one a "hydropathist" The difference is so obvious that to enlarge upon it would be to doubt the intelligence of the Society Equally great is the difference between one who sometimes uses a remedy that in healthy persons would produce effects resembling some of the symptoms of the disease, and one who assumes a title which, if it means anything, means that his everyday practice is designedly based upon the so called "law of similars" In words Dr Roberts ignores this difference, nevertheless he practically admits it, or there would have been no necessity to write his paper It does not require an elaborate thesis to demonstrate that twice two is four One needs not eloquently plead for the removal of a disqualification that he admits does *not exist*

---

[1] Proceedings vol ix, p 278, 1889 The Medical News, Philadelphia, Oct 19, 1889

Dr Roberts is doubtless correct in his repeated assertions that "very many of those whom the public regard as homeopathists have comparatively little faith in the infinitesimal doses of Hahnemann, or in the infallibility or universality of his law," and that 'to day there is comparatively little belief in or practice of homeopathy as advocated by Hahnemann" A good lawyer would have hesitated to make such admissions in a paper written in defense of homeopathists They prove, however the sincerity of our former President, a proof strengthened when he further states that the real homeopathy pays no attention to the microscopic and chemic changes in tissues and organs, but believes in selecting a remedy which causes symptoms similar to the totality of the symptoms seen in the patient"

But if this belief, which Dr Roberts very properly characterizes as "unscientific and unworthy of credence," is in Dr Roberts' own language "the real homeopathy," what kind of homeopathy is that which he says is practised by the great body of those "whom the public regards as homeopathists?" It must be an unreal, a false, a fraudulent homeopathy And Dr Roberts's proposition reduced to plain English is this "We can not admit to membership in this Society the real homeopathists because they are loyal to a dogma which is unscientific and unworthy of credence, but we ought to admit the false homeopathists because they only pretend allegience to that dogma"

Mr President, I have more respect for the honest simple-minded donkey than I have for the disingenuous and uncertain mule

There is, however, one proposition in Dr Roberts' paper with which I desire to express my full and unqualified assent, and upon the principle enunciated in which we can all, I think, find a common meeting ground I, for one, should be most happy to aid in bringing about its incorporation into the organic law of this Society Dr Roberts says 'The test of qualification for membership should not be the college from which the applicant received his diploma, but an education enabling him to understand and appreciate the science of medicine and an honest purpose to treat his patients by all means and methods which experience, investigation and research show to be serviceable"

With this opinion, let me repeat, I am heartily in accord It is quite evident, however, that such an education as Dr Roberts describes can not be received in a sectarian school, despite the use of any number of scientific textbooks, and one has only to read the first homeopathic journal that comes to hand to see that even among the "unreal" homeopathists, while they do have considerable knowledge of the empiric practices of physicians, which practices they copy more or less intelligently—very few have an adequate comprehension of the principles of scientific medicine But the most certain evidence that the official representatives of homeopathy in Pennsylvania do not "understand and appreciate the science of medicine" has been given by their demand for the establishment of sectarian examining boards Any one who elects to go before such a board, thereby declaring his lack of acquaintance with scientific therapeutics and practice and the limitation of his studies to the theories and methods justly termed by Dr Roberts, "unscientific and unworthy of credence" voluntarily excludes himself from the ranks of the profession, voluntarily enrolls himself as a sectarian We certainly can not accept the certificate of such a board as evidence of an applicant's possession of "an education enabling him to understand and appreciate the science of medicine and an honest purpose to treat his patients by all means and methods which experience, investigation and research show to be serviceable" On the contrary, it is a direct evidence of partial and narrow education, of training limited to what Dr Roberts has well termed, "unscientific and untrustworthy" theories and practice If, however, a graduate of a sectarian college after sufficient practical experience to compensate for his want of school education, should desire to enter the ranks of the profession of medicine, and should evidence his sincerity, not ouly by abandoning his sectarian designation, but also by refusing to permit his patients to apply it to him, and if after due investigation the censors should report that he was in personal character, professional knowledge, and scientific spirit, worthy of admission to this Society, it would give me great pleasure to cast my vote in his favor

To conclude the great point of dissimilarity between physicians and latter-day homeopathists is the profession by the latter of adherence to a dogma which is not only "unscientific and unworthy of credence," and an insuperable obstacle to progress, but which they themselves do not half believe in, an "unreal" profession of faith which may serve to attract patients, but which can not be considered straightforward So long as any one voluntarily makes such profession he renders it impossible for self-respecting physicians to meet him upon equal terms

If, however, one whose personal character fits him for membership in this Society but who had formerly professed homeopathy becomes convinced of his mistake, and desires to join the ranks of scientific medicine, he should be freely received, provided only that he repudiates any sectarian designation and gives to the censors satisfactory evidence of his professional attainments More than this we ought not to ask Less than this we can not honorably accept

DOMESTIC CORRESPONDENCE

Hectic Fever

Austin, Tex, Oct 9, 1893

To the Editor —After many years of special experience in the treatment of pulmonary consumption and its various complications, I find the prescription herewith enclosed the most efficient and least disturbing to combat hectic fever

℞ Phenocoll
Salicin āā gr 48
Sulphate Hydrastiæ gr 24
M ft 24 capsules

Sig One capsule every four to eight hours, as may be necessary to cool or prevent hectic fever Of course, such other treatment, local or constitutional, as may be indicated should be diligently administered

Yours truly, Q C Smith, M D

Wayne County, Mich , Medical Society

Detroit, Mich , Oct 10, 1893

To the Editor —At the annual meeting of the Wayne County Medical Society the following officers were elected for the ensuing year President, Hal C Wyman, M D , Vice President, E B Smith, M D , Secretary, R H Horner, M D , Treasurer, C Henri Leonard, M D Board of Directors J E Clark, M D , E W Jenks, M D , James Newell, M D , J E Westgate, M D , K Gunsolus, M D

Yours truly, E B Smith, Sec'y

Diphtheria

Wisconsin State Board of Health,
Office of the Secretary
Appleton, Wis , Oct 6, 1893

To the Editor —Replying to your letter of inquiry the newspaper reports of the prevalence of diphtheria in Grantsburg, Wis , have been greatly exaggerated Official reports received at this office to October 5, show that there was probably an error of diagnosis of first cases, but since the true nature of the disease has been known it has been brought thoroughly under control

There has been a total of seven deaths to above date No new cases have been reported during the past week

Very truly yours, J T Reeve, Sec'y

BOOK NOTICES

A Manual of Medical Treatment or Clinical Therapeutics —By I Burney Yeo, M D, F R C P Professor of Therapeutics in King's College, London In two 12mo volumes containing 1,275 pages, with illustrations Complete work, cloth, $5 50 Philadelphia Lea Brothers & Co 1893

This excellent work will be found very useful to general practitioners Those fond of formulæ will find them here to their satisfaction and except that the author uses the English system of weights and measures and nomenclature no fault can be found with them In these days of International Societies, the tendency is to unite on the decimal system of weights and measures, but the Englishman is always satisfied with his 'right and tight little island," and its customs, and in the nineteenth century when every nation but his own has adopted a decimal money standard, he stands aghast at any proposition to change the relative value of his absurd division of money into pounds, shillings and pence, and is utterly unable to understand that among the labor saving devices of scientific literature the decimal system ranks as chief

The pathology of the diseases treated, although brief, is quite abreast of the latest literature on the subject, and the treatment recommended is unexceptionable We notice, however, the same tendency to the recommendation of European health resorts and mineral waters, in exclusion of every other, that characterize most continental books on therapeutics One may look in vain for a single reference to any American health resort, although the European resorts are very fully considered It would be unfair to change this against this particular work, because this fault is common to all of its class Why should an American, knowing the facts, recommend Nice in preference to Asheville or Los Angeles, or Carlsbad in preference to Hot Springs? The truth is, that in the matter of advertising our own mineral springs and healing resorts, we are not in the same class with the European In that favored land, advertising has become a fine art

We have wandered into these reflections, while examining this very valuable work of Dr Yeo, and can only express the hope that when the second American edition shall be provided, the just advantages of American resorts may have their place Notwithstanding the omissions pointed out, the work is deserving a place in the library and will be a welcome addition to the literature of medical therapeutics

The Theory and Practice of Medicine Prepared for Students and Practitioners By James T Whittaker, M D, LL D, Professor of the Theory and Practice of Medicine in the Medical College of Ohio, Lecturer on Clinical Medicine at the Good Samaritan Hospital, Fellow of the College of Physicians of Philadelphia, Member of the Association of American Physicians, of the American Academy of Medicine, and of the American Medical Association With a Chromo Lithographic Plate and three hundred Engravings Octavo, 840 pages, Extra muslin price, $5 75, leather, $6 50 New York William Wood & Company

It is customary for the unthinking to consider that surgery alone has profited by the wonderful discoveries of Pasteur, but a glance at the frontispiece of Dr Whittaker's book and at the text of the various articles will convince the most skeptical that this bacteriological epoch has revolutionized the practice of medicine not less than that of surgery

The author fully accepts the microbic theory as applied to general medicine He says in regard to malaria

'Malaria has for a long time been supposed to be caused by a '*contagium vivum* with no other positive proof however than the isolated experiments of Gerhardt of Berlin, who succeeded in producing the disease by injecting blood from the spleen of an affected individual into the veins of a healthy man All efforts to discover any demonstrable and acceptable cause of the disease remained futile up to the time of the investigations of Laveran 1881 a French military surgeon of Algiers who succeeded in discovering in the red blood corpuscles peculiar amœboid bodies endowed with characteristic protoplasmic motion, and containing granules of pigment matter Certain smaller bodies, of irregular, semi lunar or *crescentic outline are also found in the* blood plasma connected together often by fine thread These bodies are present in the blood of malaria in greatest abundance during a chill and disappear to a great extent after the attack Many of them are clear, more or less spherical, sometimes flagellated, hyaline masses undiscoverable without the use of dyes They gradually increase in size until they fill the body of the corpuscle during which process they undergo peculiar segmentation The intra corpuscular body receives the name, *plasmodium* Besides the plasmodium, flagellate structures with three to eight long active cilia, may be seen floating free in the blood of more acute cases or may be discovered in the blood drawn from the spleen, which is regarded as the hotbed of malaria in the body Golgi claims that the various types of fever, anomalies etc depend upon peculiarities or differences in these parasites, and Laveran maintains that the crescentic forms are found only in inveterate and cachectic cases So too, it is said that quinin destroys only the plasmodium, and that arsenic has more effect on the crescentic form Concentrated aqueous solutions of fuchsin and methylene blue are the best staining agents for ordinary diagnosis "

We have quoted this paragraph thus freely that it may be seen how far the old lines have been cast off

There is some lack of precision in the composition and a faultiness of style, for example "Diseases of the mouth for the most part reveal themselves readily to inspection Daylight is the best," etc, whether daylight is the best inspector, the best disease or the best revealer is uncertain, but here as elsewhere, the average reader knows what impression or idea the author means to convey The charm of the textbooks of Watson and of Flint lies in their clearness of expression and their precision, scarcely less than in their choice of words, the first two characteristics, the reader has a right to expect of all authors the last is a gift of the gods to the few, and is not essential

The work under review is without question the most original that has appeared on the subject for a long time, and the defects of composition that we have pointed out are so trifling in comparison with the great merit of the work, that we only mention them to insure their avoidance in the next edition, which we predict will speedily follow

New York County Medical Association Register of Members and Manual of Information 12mo cl pp 116 Published by the Association New York 1893

This is an official list of the members of the New York County Medical Association, and as well the names of "other practitioners of rational medicine resident in the City and County of New York

Unfortunately in the State of New York, and *there only*, the regular profession is divided, the meridian line being the American Medical Association and adherence thereto In the existing *division* the New York County Association adheres to the National organization, and thus cooperates with the profession as it is maintained in all the other States of our common country "

A history of the recent effort by the American Medical Association to restore harmony is briefly recited

Medical Society of the State of Washington —Transactions for 1893 This little volume records the proceedings of the Fourth Annual Meeting The papers are well written and show that our occidental brethren are quite up to the professional mark Dr G D Shearer of Tacoma, is the Secretary

Wisconsin State Medical Society Transactions —The annual volume of the Wisconsin State Medical Society lies on our table It is well printed and contains some excellent papers, many of which exhibit much painstaking, original work The Transactions compare favorably with those of other States Dr Chas S Sheldon of Madison, is Secretary

Syllabus of Lectures on the Practice of Surgery Arranged in conformity with the 'American Textbook of Surgery," by N Senn, M D, Ph D L L D Flexible covers, cl pp 221 Philadelphia W B Saunders 1894

This well-arranged syllabus of a system of lectures on surgery will be found very useful to teachers and students

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

SUBSCRIPTION PRICE, INCLUDING POSTAGE
PER ANNUM, IN ADVANCE $5 00
SINGLE COPIES 10 CENTS

Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
NO 68 WABASH AVE, CHICAGO, ILLINOIS

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION

This is obtainable, at any time by a member of any State or local Medical Society which is entitled to send delegates to the Association All that is necessary is for the applicant to write to the Treasurer of the Association, Dr Richard J Dunglison, Lock Box 1274, Philadelphia, Pa, sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society with five dollars for annual dues and subscription for THE JOURNAL Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly

All members of the Association should send their Annual Dues to the Treasurer RICHARD J DUNGLISON M D Lock Box 1274 Philadelphia Pa

SATURDAY, OCTOBER 21, 1893

QUARANTINE IN CANADA

With reference to the World's Fair exhibit of the models of the disinfecting chambers in use at the St Lawrence quarantine the following will be of interest

Grosse Isle, about 700 acres in extent—larger than the grounds covered by the World's Fair—and thirty-one miles below Quebec, was purchased and equipped as a quarantine station in 1832, when cholera first visited this country It was then provided with the best means and methods for the ends in view at that time known There still remains a massive and roomy hot air disinfecting oven It had also a liberal supply of detention and isolation buildings, wash houses, etc The presence and use of these appliances and buildings provided all that sanitary science of that day considered requisite for a first class quarantine station during the sailing vessel period They rendered it then and for many subsequent years the best equipped quarantine in the world

The importance of this station will be appreciated when it is stated that in one season alone—the ship fever year, 1847—an immigration of more than 99,000 was dealt with there from May to September The hospital records for that time show an admission of over 8,000 sick A little monument in the cemetery bears witness to 5,424 interments in that short season alone

Following the change from sailing vessels to steamships, as immigrant carriers, and the advancements in sanitary science, the station has been equipped with all the requirements of modern maritime sanitation It has now three steam disinfecting chambers 25×8½×8½, double jacketed and fitted with steam gauges, vacuum pumps, electric contact thermometers, registering dials, etc, for the disinfection of clothing and luggage In connection with these are three sixty-horse power boilers for steam supply, with feed pump, settling tank, etc Above these chambers, in the second story, are twelve rain or needle baths for the personal washing of the suspected, while their clothes are passing through the steam chambers

A detention building has been erected to give saloon passengers the same accommodation as they have in a first class steamship Two buildings have been adapted with staterooms, baths, etc, for second cabin passengers, and the steerage buildings have had their wooden bunks replaced by galvanized iron beds There is for this class of passengers also an ample supply of baths and water closets These buildings, a mile and a half from the hospital division, provide for the detention and isolation of 128 saloon, 200 second cabin and 1,500 steerage passengers There is also a bacteriological laboratory Two powerful steam pumps supply water from the end of the pier to a 50,000-gallon reservoir from which it is piped to the buildings for all but drinking purposes An artesian well is being sunk for potable water, and there is a condensing and aerating apparatus in connection with the boilers calculated to yield a daily supply of 2,000 gallons The disinfecting steamer and the inspecting steamer are fully equipped with the most modern appliances, including steam hose, mercuric chlorid solution drenches, a sulphur dioxid blast furnace, etc

All vessels are inspected at Grosse Isle or, in the case of mail steamers, at the advance inspection station at Rimouski, 150 miles below, where the mails are landed If, upon inspection a vessel is found to be infected, it is dealt with at the Grosse Isle station, if found healthy it is allowed to proceed and land its immigrants at Quebec, or Levis opposite Quebec At these sub-stations *all* the immigrant luggage from healthy vessels passes through steam disinfection before it is allowed to be checked or forwarded More than one hundred thousand pieces of luggage from healthy vessels have been so disinfected already this season The plant for this purpose, at the Quebec landing place, is similar to that already described for Gross Isle, except there is one chamber instead of three

It may be added that Halifax, Nova Scotia, St John's, New Brunswick, William's Head, in the Straits of Fuca, and the Province of British Columbia on the Pacific coast, have been similarly equipped with all these recognized requirements, rendering them also quarantine stations of the first class

From the foregoing it will be seen that the utmost care is being taken by the Dominion of Canada to protect herself and her neighbors against the introduction of contagious diseases

---

HOSPITAL GROUNDS TO BE BISECTED —The trustees of the Episcopal Hospital of Philadelphia are up in arms on a proposition to bisect the hospital grounds by the city extension of Fillmore Street

THE LIMITATION OF TUBERCULOSIS

In our last week's issue we published an account of the action of the Michigan State Board of Health, by which the physicians of that State are hereafter required to notify the local health officer of the existence of consumption and all other diseases due to the *bacillus tuberculosis*, the same as in cases of smallpox, scarlet fever or diphtheria The local health officer is to notify the State Board, and the State health officer will then give such instructions relative to restrictive measures, as the nature of the case and stage of the disease seems to warrant The Board has already issued a pamphlet perhaps generally applicable, showing how to restrict these cases

The great increase in the number of cases of tuberculosis throughout the country makes it desirable that some means of limiting the ravages of the disease be systematically undertaken, and if this move of the Michigan State Board shall prove beneficial, even in slight degree, the whole country will come into line

The cause of tuberculosis being well known, and its mode of transmission thoroughly understood, there is no longer reason why determined effort should not be made to stay the ravages of this dire affliction In consumptives, the care of the sputum, the mouth disinfection, the disinfection of all excreta, and the careful disinfection of the wearing apparel, are most valuable means of preventing the spread of the disease from the patient to others

Personal restriction is a harsh measure, and should only be required in very advanced cases, those, in other words, that are better off when kept quiet, but there is surely reason enough for requiring the sick man to keep away from crowded assemblages and public conveyances There is undoubtedly danger to the public health in allowing a patient with advanced phthisis to mingle freely with crowds, and contaminate the air with the products of expiration in public conveyances The expired air coming direct from the lungs, more or less charged with tubercle bacilli, is as fruitful a source of propagation of the disease as could well be imagined

It is not to be expected that the same limitation can be effected on other forms of tuberculosis, especially those of the bones and joints, and yet in many cases there comes a period in the history of these cases when there is generally disseminated tubercle, and often the same condition develops in the lung as in cases of primary lung infection

The success or failure of these efforts of limiting the spread of tuberculosis, happily begun by the Michigan Board of Health, can not be determined for at least a twelvemonth It is fortunate, however, that the system of registration in use in Michigan is so complete that we shall, soon after the year's trial, have definite and conclusive figures

CHILD LABOR CERTIFICATES

Many members of the medical profession are doubtless unaware of the enactment in Illinois of a very effective law, placing the duty of inspection of factories in which children are employed under a superintendent The law absolutely prohibits the employment in factories of children under fourteen years of age It provides that all children between fourteen and sixteen shall have a certificate, from an authorized physician, asserting that they are in such health and in such a state of development as to permit them in the judgment of the physician to work in the factories without danger This certificate must assert that the physician has examined the applicant and seen him at work, and that he considers him able to do the work proposed without detriment to his subsequent health In the operation of this law, children have brought to the inspector, certificates from physicians who have evidently made them in a perfunctory way, either entirely ignoring the condition of the applicant or having never seen him at work as the certificate requires It must be remembered that this law is intended to prevent the premature decay and the arrest of development of our young factory laborers, and it is intended in this way to diminish the subsequent expenditures of the State, the county and the city in the care and maintenance of the defective classes It is only necessary to invite attention to some of our more destructive trades, in which children are employed, to make apparent the wisdom of this provision Incidentally these requirements would keep the labor of children out of the market and prevent undue reduction of the wages of adults through the competition of child labor The physician, in examining the child, should thoroughly compare him with the well fed and well developed child of his age He should pay special attention to the development in those directions most apt to be arrested by the trade into which the child is going, and by the position in which he will be required to work The physician should do his work conscientiously, knowing that if he neglects his duty in this matter, the wreck of humanity which is likely to result, will have to be maintained in wretchedness at the expense of his own children when they come to manhood and womanhood and become taxpayers The physician should in no circumstances sign these certificates until he has actually seen the child at work in the factory for which the certificate is required

THE HEALTH OF AMERICAN WOMEN

Elsewhere in our columns PROF EDMUND ANDREWS gallantly defends our American women from the aspersions cast upon them by DR CYRUS EDSON who in a recent number of a monthly magazine held them up to popular condemnation for alleged physical deterioration and defective training

We doubt not that other defenders will break a lance in this fray under the leadership of PROF ANDREWS in case it shall be necessary, but at present it seems that as DR EDSON'S charges against American women were based on mere assertion, while PROF ANDREWS supports his opinion by figures, the latter has decidedly the better side of the question, and should receive the thanks of the women of America for his timely and prompt defense

ABSOLUTE ALCOHOL FOR SCIENTIFIC PURPOSES IS DUTY FREE

The decision of the United States Circuit Court, S D New York, *in re* Kny, rendered June 27, 1893, is just reported in 57 Federal Reporter, p 190, affirming the decision of the board of general appraisers, which reversed the classification of the collector of the port of New York on certain so-called "absolute alcohol" The latter classified it as "alcohol, 198 degrees, $4 95," at $2 50 per proof gallon, under the provisions of paragraphs 329 and 333 of Schedule H of the tariff act of October 1, 1890 Against this classification the importers protested, claiming that the article was a scientific preparation for college use, and duty free, under paragraph 677 of the free list of said tariff act This "absolute alcohol" was made by chemical action by adding lime, and then distilling the liquid over again, by means of which the high percentage of 99 5 of alcohol was obtained, and was from two to three times higher in price than the regular alcohol of commerce, running only to 95 per cent That it was "not intended for sale," within the meaning of said paragraph 677, was to be understood that it was not intended to be disposed of by sale to any other person than the corporation or society for whose special use the importation was permitted to be made, though in this case it was admitted that the importers' profit in furnishing the article to the colleges in question was about 20 per cent

RIGHT TO USE GEOGRAPHICAL NAMES FOR MINERAL WATERS

Whether a geographical name may become a trademark, when adopted as such, where its owner is the owner of the place of origin, and has the monopoly of the vendible product, is an open question But where a person alleges title to all the mineral springs situated in a certain place, and the exclusive right to the sale of the waters thereof, and that the name, as applied to said waters, has become of great value to him, and has always constituted an important and necessary incident and means to the sale of said waters, that such a name may be so used, and will be protected against infringement by other persons not obtaining their product from the same locality, is well settled So says the United States Circuit Court in the case of La Republique Francaise v Schultze, decided July 3, 1893, just now reported, 57 Fed Rep 37, where it holds that the word "Vichy," used in connection with mineral waters, and derived from the locality in France where the waters are obtained, is a trade name, or "nom commercial," within the meaning of the industrial property treaty with France of 1883, and as such is entitled to protection in the United States though it has not been deposited as required by the treaty in the case of trade-marks

TRY A NEW NAME

We suggest that some of the "Tri-State" societies *try* a new name to avoid triangular confusion We now have a Tri State Society of the brethren of Missouri, Iowa and Illinois, another of Indiana, Kentucky and Illinois, another of Arkansas, Tennessee and Mississippi, and another of Alabama, Tennessee and Georgia There is room in the AMERICAN MEDICAL ASSOCIATION for all of them, and all would be stronger if united in one great body The great need of the profession is organization, and medical men should join the parent medical Association on the broad ground of mutual scientific interests and material advancement The door is always open to members by application at any season We hope each member may aid the great movement now going on, which has for its object the formation of one of the most powerful medical associations of the time, in the AMERICAN MEDICAL ASSOCIATION

SOCIETY NEWS

Twenty-first Annual Meeting of the American Public Health Association in Conjunction with the International Congress of Public Health

Abstract of the Proceedings of the Joint Sessions of the Congress, held in Chicago, Ill, Oct 10, 11, 12, 13 and 14, 1893

OCTOBER 10—FIRST DAY—MORNING SESSION

The Congress convened in Hall Seven of the Memorial Art Palace, and was called to order by the President of the World's Congress Auxiliary, the Hon Charles C Bonney of Chicago, at 10 30 A M

Prayer was offered by the Rev Dr Parsons, after which addresses were delivered by Hon C C Bonney, Mrs Charles Henrotin, Dr A R Reynolds, Commissioner of Health of Chicago (representing the Mayor), Dr E Liceaga of Mexico, and Dr Sarah H Stevenson of Chicago

Mr Bonney then introduced Dr S H Durgin of Boston, President of the American Public Health Association, as President of the Congress, who replied briefly to the several addresses after which he delivered his Inaugural Address (See October 14th issue of THE JOURNAL, p 551)

After some announcements by Dr Brewer, the Congress adjourned until Wednesday morning

OCTOBER 11—SECOND DAY—MORNING SESSION

The Congress was called to order at 10 A M by the President

The first paper read was by DR ALBERT L GIHON, Medical Director U S N, entitled, "Sanitary and Medical Service on Emigrant Ships"

REPORT OF THE COMMITTEE ON RESTRICTION AND PREVENTION OF TUBERCULOSIS

This report was read by the Chairman of the Committee, Dr J N McCormack of Bowling Green, Kentucky The Committee offered as its report the following conclusions and recommendations

1 Tuberculosis has been conclusively demonstrated to be contagious, by bacteriological experiments, by clinical observations, and by a study of the history of the disease

2 Tuberculosis is a preventable disease Its preventability follows as a logical sequence upon its contagiousness, but has likewise been demonstrated in practical life

3 The contagium of tuberculosis resides entirely and solely in broken down tubercular tissue A person suffering from tuberculosis, therefore, does not become a source of danger to others until he begins to give off broken down tubercular tissue, either in the form of sputa from the throat or lungs, diarrheal discharges from the bowels, or matter from a tuberculous sore such as lupus, white swelling, cold abscess, scrofula or tubercular inflammation of a joint

4 A person suffering from tuberculosis can be made entirely harmless to those about him by thorough sterilization of all broken down tissue immediately upon its being given off With proper precautions it is therefore possible to live in the closest relation and upon the most intimate terms with consumptives without contracting the disease

5 Tuberculosis is not hereditary A predisposition to the disease can be transmitted from parent to offspring, but this is more true of tuberculosis than it is of all other contagious diseases

6 A predisposition to tuberculosis can be created anew by malnutrition or by anything which depresses the nervous system

7 Tuberculosis affects animals as well as man, and is identically the same disease in both In domestic life human beings and animals mutually infect each other

8 The media through which human beings are ordinarily infected by animals are milk and meat

9 Houses in which consumptives have lived and in which immediate sterilization of all broken down tissue has not been practiced, are infected houses and are liable to convey the disease to subsequent occupants

10 Spitting upon floors and into handkerchiefs, and permitting the broken down tissue to dry and become pulverized is a prolific cause of spreading tuberculosis

11 Temporary occupation of hotel rooms, sleeping car berths and steamer cabins by consumptives in the infectious stage can infect them so as to convey the disease to subsequent occupants, unless proper precautions are taken against contamination of the bedding, furniture and walls with broken down tubercular tissue

We recommend the following practical measures for the prevention of the disease

1 The notification and registration by health authorities of all cases of tuberculosis which have arrived at the infectious stage

2 The thorough disinfection of all houses in which tuberculosis has occurred, and the recording of such action in an open record

3 The establishment of special hospitals for the prevention of tuberculosis

4 The organization of societies for the prevention of tuberculosis

5 Government inspection of dairies and slaughter houses, and the extermination of tuberculosis among dairy cattle

6 Appropriate legislation against spitting into places where the sputum is liable to infect others, and against the sale or donation of objects which have been in use by consumptives unless they have been thoroughly disinfected

7 Compulsory disinfection of hotel rooms, sleeping car berths and steamer cabins which have been occupied by consumptives, before other persons are allowed to occupy them

The reports and recommendations of the Committee were adopted

TROPICAL DIARRHEA

This paper was contributed by Sir Joseph Fayrer of London England, and read by Dr Gihon

This is a form of disease which is generally, if not always, the result of tropical and climatic influences and the debility and cachexia induced thereby It is now not infrequently observed in Europe, owing to the ever increasing means of communication with foreign countries It is apparently generally confined to adults, is insidious in its onset, slow in progress, and often when not arrested sufficiently soon, fatal, owing to irreparable degenerative changes It has been described by many observers both English and foreign, in India, China, Cochin China and Batavia Most of the cases seen in this country come from India, China or Ceylon In India it is met with frequently, where a form of it is known as 'hill diarrhea," from its proneness to affect dwellers in hill stations, especially those who have previously lived in the plains, atmospheric changes, vicissitudes of temperature, greater altitude, rarefied atmosphere and possibly water being concerned in its causation Some authors consider it a distinct disease from the white flux which may be seen in any part of the country, but they are so much alike as to justify the belief in their identity, at all events for practical purposes Occasionally there is a resemblance to certain forms of chronic dysentery, the two conditions may be associated or one may merge into the other

Tropical diarrhea occasionally makes its appearance years after the subject of it has returned from the tropics It not infrequently begins without any previous apparent derangement of health, though it is sometimes preceded by dysentery, diarrhea, some indication of malarial infection or functional derangement of the liver or other abdominal viscera, and is not noticed until excessive soreness of the tongue and loss of strength and wasting reveal the gravity of the condition

Semeiology —This form of diarrhea may begin with simple looseness of the bowels, or may supervene on ordinary diarrhea or chronic dysentery The action produces a sense of relief The dejecta at first may be natural and bilious, but gradually become light colored, frothy, pultaceous and copious As the disease advances they are occasionally tinged with blood and the sufferer becomes more attenuated, exhausted and incapable of any prolonged exertion The appetite may be good, but rawness and tenderness of the mouth and tongue frequently accompanied by aphthous spots and ulcerations interfere with its gratification

Treatment —From the insidious character of the disease, tropical diarrhea not infrequently gains ground before radical measures for its relief are resorted to Successful issue depends much on the patient's resolution and perseverance in carrying out instructions Alternations of temperature, errors of diet, fatigue or excitement exertion, mental or physical, should be avoided Physiological rest should be insisted on

There is a tendency in the earlier stages to get well The object is to favor this tendency and not thwart it by neglect of precautions Diet is the most important consideration and must be strictly regulated and adhered to, and scarcely less important is the question of clothing, habits and modes of life Milk *alone* should be the only diet, and it must be given in small quantities often repeated, say from four to six ounces every hour, day and night Larger quantities at longer intervals will not do When in the twenty four hours an adult is able to take three to four quarts of cow's milk in this way ample nourishment is afforded to support his strength and to enable him to recover This method of treatment was begun by the author before his leaving India in 1872 After prolonged experience and trial of all other forms of remedy, he has found it more effective than anything It seldom fails except in the very advanced and chronic cases, or in very aged persons The conclusion arrived at is that though drugs are generally of little avail, if milk, taken as prescribed, does not succeed, there is but small chance that any other form of treatment will do so

CHOLERA INFANTUM AND ITS TREATMENT

By Dr Manuel Septien of Queretaro, Mexico

The treatment proposed is exceedingly efficacious It consists in the total suppression of all food and medicine during twenty-four or forty eight hours, and the prescription of pure cold water in great abundance The author said there is scarcely any disease that causes a greater mortality in childhood than that known by the name of estival diarrhea or infantile cholera In one single week the last one of July of the present year, there were 1,126 deaths in 33 of the largest cities of England, caused by this disease alone Statistics show everywhere a notable increase in the number of deaths during the months of June, July and August, that is to say, during the warmest season of the year The malady is not limited to children only, but attacks also a great number of adults and old people, being less mortiferous in the latter than in the former, in whom it causes a mortality of 50, 60, and even 80 per cent Only Asiatic cholera, to which it has the greatest similarity, can be compared to it for its ravages It is undoubtedly of microbic origin as recent investigations have shown

Energetic drainage is the supreme effort which nature executes to rid the organism of the deleterious elements that poison it To try to suppress it by therapeutical means is not an easy or rational thing to do It would only hinder the natural curative process The only thing that can be done is to oppose the extreme dehydration of the tissues by restoring to them without delay at least a part of the water lost This is the therapeutical indication, and no drug can take its place, nothing but pure cold water

All the curative methods tried leave much to be desired Their results are very uncertain, all consist in the administration of various medicinal substances, non astringents, absorbents, antiseptics or anti-peristaltics, and in the prescription of some alimental regimen Such treatments, according to the author, are not in conformity with the great principle that governs therapeutics, namely *the physiological rest of the organ that suffers*

The author had practiced successfully the treatment recommended by Luton of Reims He summarized the points of his paper as follows 1, to suppress all nourishment and medicine for one or two days, 2, to give at discretion pure cold water, 3, to return by degrees to a rational regimen

ORIGIN AND DISSEMINATION OF TYPHOID FEVER

By **Professor W T Sedgwick** of Boston Professor Sedgwick's remarks on this subject were impromptu He first dwelt upon the reorganization of the State Board of Health in Massachusetts in 1886, shortly after which an experiment station was established at Lawrence for the purpose of studying typhoid fever chemically and bacteriologically, and looking to the purification of the water In 1890 an epidemic of typhoid fever broke out upon the Merrimac River in the city of Lowell, and shortly afterwards appeared at Lawrence, nine miles below These epidemics afforded unusual opportunities for the investigation of the epidemiology of typhoid fever

SECOND DAY—AFTERNOON SESSION

Mr Allen Hazen of Lawrence, Mass, read a paper entitled

THE SEWAGE DISPOSAL PROBLEM IN AMERICAN CITIES

He said one of the striking features of the sanitary development of American cities is the very rapidly increasing number of places which for one reason or another are treating in some way their sewage It is not so many years since there was hardly a sewage purification plant in the United States, while at the present time there are some thirty municipalities in a dozen different States which give their sewage a more or less thorough treatment Of these a number are in the far West where the sewage has a commercial value for irrigation which has probably been considered quite as important as the sanitary advantages secured by the treatment, but the greater number are in the East, where a dense population and increasing desire for cleanliness in the waters of streams and lakes, and particularly in water supplies, has brought to an issue problems which as yet have scarcely received the attention of the inhabitants of the less thoroughly settled States

There are two sewage problems which are entirely different in their nature, although the same remedies may often be applied to both There is first the pollution of rivers and lakes to such an extent that they produce a nuisance to the people who live upon their banks, and secondly the pollution of water supplies by sewage The first case is often that of a city upon the banks of a small river which becomes so reduced in volume in dry weather that the sewage may fairly be said to be the predominating element in its composition Up to a certain point, rivers are capable of taking sewage without causing a serious nuisance to the people who live upon their banks, so long as they do not drink from them, but when this quantity has passed, deposits are formed, decomposition sets in, and the stream is rendered foul in appearance and objectionable in its odor The exact quantity of sewage which can be mixed with water without causing a nuisance varies with local conditions and can only be approximately estimated, but as long as the limit is not passed, and the bodies of water not used for drinking, the disposal of sewage by turning it into such water is entirely unobjectionable and by far the most satisfactory method possible

Where the sewage of a town is entering the public water supply of a neighboring town, or worse yet, its own supply, the problem is entirely different The removal of the organic matters of the sewage becomes of secondary, although still an important matter, while the removal of those germs of disease, which would otherwise work such mischief among the consumers of water becomes the one important point

The author then dwelt upon the possibility of sewage treatment by chemical precipitation, which he said was the same the world over Local conditions are only of secondary importance The experiments undertaken by the Massachusetts State Board of Health at the Lawrence Experiment Station, some six years ago, indicated that the local conditions in Massachusetts would allow the treatment of sewage upon land even with more favorable results, both as to quantity of sewage treated and quality of effluent obtained, than had been supposed to be the case from a study of European practice

It is impossible, by any combination of chemicals, to secure the purification which approaches even remotely the result obtained by land treatment, but when the problem is simply to keep the water into which the sewage flows reasonably clean, the result with careful manipulation is quite satisfactory When, however, the treated sewage finds its way into the source of the public water supply, the effluent produced by even the most complete chemical precipitation can not be regarded as an entirely unobjectionable addition, and such water should be further treated by filtration before use

THE COLLECTION AND DISPOSITION OF ANIMAL AND VEGETABLE WASTE IN THE CITY OF MILWAUKEE

By **Dr U O B Wingate**, Commissioner of Health of Milwaukee As early as 1879 the city of Milwaukee began to grapple with the garbage problem, and it has been a long and serious struggle until a recent date In the winter of 1891 and 1892, the State Legislature passed an act authorizing the Common Council of the city to enter into a contract for the disposition of garbage, with the advice of the Mayor and the Commissioner of Health It was decided to let the contract for five years to a company who would build a plant fourteen miles out of the city, collect and remove to said plant all garbage, offal, dead animals, both great and small, and animal matter of the city of Milwaukee, including refuse matter from the commissson houses, etc, to said plant in which they would dispose of it in a sanitary manner This contract went into effect and the work was commenced in June, 1892

The Company constructed a plant at an expense of some $110,000 They purchased a powerful steam barge for transportation, they put on fifty steel, air tight wagon tanks for collection and two large covered wagons for the collection of large dead animals Since the first of September, 1892, the plant has been in operation to the satisfaction of the city officials of Milwaukee, creating no nuisance or stench whatever that can be reasonably objected to in its location, and the collection and transportation of the material during that time has been fairly satisfactory

DISPOSAL OF GARBAGE AND WASTE OF WORLD'S COLUMBIAN EXPOSITION

By **Col W F Morse** of New York Since the meeting of the American Public Health Association two years since, marked progress has been made in the destruction of garbage and waste of cities by fire Six years' experience has shown this method to be of far greater value than any other, and improvements in furnaces and reduction in cost of operation have steadily made it more popular and useful

England has now furnaces in every large city and the number is yearly increasing This country is awakening to the value of this method, and it has been inspected and recommended at a great number of places The most striking and effective work done in the world is at the World's Fair where two furnaces of the Engle Sanitary Company have been at work since the first of May It was early seen that the sanitation of the Fair, the care of the health of the great multitudes resident and who would come as temporary guests, would demand the best, and only those which had been thoroughly tested, methods of providing for the drainage, and the collection and disposal of the great mass of daily accumalating garbage and organic waste After the drainage was arranged the question of sewerage disposal and garbage destruction came up A contract was made with the Engle Sanitary Company of Des Moines ard New York, for two garbage cremators to burn 100 tons of sewerage sludge, garbage and stable refuse These two furnaces were built in the fall and at the opening of the fair were ready for work They are in the extreme southeastern part of the grounds, near the Forestry Building, back of the power house of the Intramural Railroad, employing the well-known device of the Engle Company, two fires, one at either end the one burning the mass of garbage on the grates, the other destroying-the smoke, and all results of this combustion These furnaces have been in constant work every day since May 5

The garbage is brought at night from 11 P M to 8 A M, and placed at once in the furnaces From twenty-five to forty loads each of one ton having sometimes ashes or water in large amounts mixed therewith Everything goes into the furnaces—four horses, two camels, cows, deer, elk, pigs, goats, dogs etc, all follow the same road and are burned with equal ease No results can be seen from the chimney A thin, invisible, carbonic acid gas, discharged at a temperature of 1,000 degrees is all that results No smoke, no odors, nothing that can be offensive is detected Though in daily use an observer would not know any work was done, unless he came to the building At 10 A M the loads of sewerage cake begin to come This is a thick, heavy, soggy mass of lime, fecal matter, paper pulp, etc, with 60 per cent of water mixed The quantity varies from ten to eighteen or twenty-five tons, and is the most refractory material to burn yet found The fires are oil fed by jets of air a pressure of twelve ounces of air doing the same work that is done in the boiler house with 120 pounds of steam The ashes are used by Exposition people for filling low places, though they have a value of $10 per ton for fertilizers

There are six burners spraying oil, the whole using thirty-seven and one-half gallons per hour The cost for fuel and labor is from 75 to 80 cents per ton for sewerage sludge and 50 to 70 cents for garbage

At other places where these same furnaces are used, the cost is reduced by bringing to the furnace, the paper sweepings, and all kinds of city combustionable waste which makes fuel to burn wet matter and reduces the cost of from 12 to 15 cents per cubic yard or 30 to 40 cents per ton Official reports from Savannah were read showing the cost for last eight months to be 11 cents per cubic yard

The work has been continuous, no stoppage, no nuisance, performed under observation of thousands of persons, inspected by many interested in this work from abroad, and has met with deserved credit and favor from the Board of Administration By adoption of similar furnaces at four points in Chicago the whole garbage nuisance could be abolished, the same work done for the city that is here performed at a reduced cost and the vexed problem of garbage disposal settled and got rid of once for all This is no theory or experiment This company was asked to do this work because they had demonstrated elsewhere their ability There are forty furnaces, or more, built by the Engle Company and in successful operation, more than twenty times as many as have been built by others, but this is the most successful instance of the destruction of garbage on a large scale that has been seen in this country

HOW CAN WOMEN PROMOTE PUBLIC SANITATION?

By Dr Sarah H Brayton of Evanston, Ill She said as instructors in hygiene, nurses have a wider scope for sanitary reform than physicians, living as they do with the families they attend, their opportunity for the diffusion of knowledge is greater Undoubtedly there is much that women could do on health boards, there is more that they must do among their own sex to increase the sum of sanitary knowledge among all classes and promote intelligent cooperation with health authorities, whoever they may be

THE PROGRESS OF SANITARY KNOWLEDGE AMONG THE WOMEN OF ENGLAND

This was the title of a paper contributed by Lady Priestley of England, and was read by Mrs Henry Wade Rogers of Evanston The author of the paper went back twenty years when she first joined the Executive Committee of the National Health Society, and attended the meetings in a small, dingy, draughty room in a house about as unsanitary as any to be found in London, and traced the progress made in sanitary science from that time to the present The author would impress upon all mothers, and those who are responsible for the welfare of others, the desirability of giving personal care and forethought, which alone can avert the consequences of unsanitary surroundings

NOTES ON CHOLERA AND ITS MANAGEMENT IN HULL, ENGLAND

This was the title of a paper contributed by Dr John Wright Mason, Medical Officer of Health in Hull, but was read by Dr Charles N Hewitt of Minnesota, in the absence of the author

The first epidemic of cholera occurred in 1832, but the total number of deaths from the disease did not exceed 270 On the 10th of August, 1849, the great visitation of the disease commenced The total number of cholera and diarrhea victims during the invasion was 1,860, being one in forty-three of the whole population of 11,000 Six hundred persons died from cholera alone, in one week in September The average age of the victims was from 30 to 36 years of age Of the total number of deaths recorded, 1,738 belonged to the laboring classes and 122 to the wealthy The greatest mortality occurred in those parts of the town where the levels were the lowest, and in which the unsanitary surroundings were the most noticeable It is recorded by an eminent minister that on one day—Black Sunday—he himself interred no less than forty three bodies of his fellow citizens The water supply was at that time obtained from the stone ferry waterworks, situated one and a half miles from Hull and two and a half miles from the mouth of the river, the water being obtained from the River Hull, the widespread character of the epidemic being greatly attributed to the impurity of the river water Since 1849, Hull has increased both in wealth and population, and its area has been considerably extended The number of emigrants passing through the port en route for America has averaged between 50,000 and 60,000 yearly during the past ten years The infectious diseases (notification) act, 1889, has been applied to the port as well as to the urban authority Measles was included among the notifiable diseases on the 10th of February, 1893

Cholera follows the line of international communication, and with the modern increased facilities for rapidity of transit, so is the danger of its possible invasion increased by emigration or otherwise England does not depend upon the false security of quarantine but rather upon its sanitary administrations, and each district should be in such a state of sanitary preparedness that the disease if imported should not spread The experience of 1892, during the epidemic at Hamburg, in those ports which were exposed, and possibly none more so than the port of Hull, which was in daily communication with that cholera stricken city, must have inspired confidence in the public mind in this country and the continent of Europe, that medical inspection, the due regard for the rigorous inspection of all articles likely to convey infection, improved sanitation and efficient hospital equipment were alone sufficient to arrest the progress of the disease Our first line of defense against the introduction of cholera consists of the medical inspection upon arrival both by day and night, of all vessels from cholera infected or suspected ports, and should cholera have developed during the voyage among any of the passengers or crew, the removal of the patients to hospital, the isolation of suspected cases and the detention on board the vessel of such persons who may be in a filthy or otherwise unwholesome condition, and who can not satisfy the medical officer of health as to their place of destination

The second line of defense against the possible introduction of cholera, or other diseases should be well protected, and the early preparations against the means by which such diseases if imported, spread, should be studied, thought out and perfected in the interim, and not during epidemic prevalence and excitement Special attention should be directed towards a pure and unpolluted water supply, the periodical and regular removal of all excreta and refuse matters in the midst of populations, the frequent flushing of all drains and sewers, the prevention of overcrowding, the systematic inspection of common lodging houses, and lastly but not least, our food supplies

Hull is essentially a privy town The death rate of Hull from all causes for the ten years, 1882 to 1891, averaged 20 7 per thousand The death rate from fevers during the same period was equal to 1 26 per thousand, and for diarrhea alone 1 10 per thousand

The author then dwelt upon the management of cholera The precautions which are adopted in Hull of what has been described as "the movement of a sanitary column," as follows

Immediately upon the receipt of a notification of cholera, or of sudden illness of a choleraic character, either by the medical practitioner in attendance, the sanitary inspectors or the police, the medical officer of health is communicated with and immediately visits the case, or in his absence his assistant Should the case admit of removal the horse ambulance, fully equipped with trained men in attendance is immediately requisitioned by telephone The assistant inspector of nuisances for the district in which the case occurs is forthwith acquainted, and makes his appearance with a column comprising flushers, lime washers and disinfecting staff He superintends the removal of the inmates of the house to the hospital for the purpose of bathing, and the disinfection of their clothing, the disinfection of the house, together with all articles of bedding, clothing, etc, which have been exposed to infection, and the destruction of such articles as may be ordered by the medical officer of health or his assistant The contents of the privy are removed to the destructor for cremation and the interior cleansed, disinfected and lime washed The subsidiary drains in the immediate contiguity of the house are thoroughly flushed, and disinfectants are freely distributed in the neighborhood of the outbreak

EVENING SESSION

At this session Dr George M Sternberg, Surgeon General of the United States Army, delivered a stereopticon lecture on "Pathogenic Bacteria" Slides of the typhoid bacillus, the bacillus of anthrax of tuberculosis, of glanders, of tetanus, of influenza, of hog cholera, etc, were shown

OCTOBER 12—THIRD DAY—MORNING SESSION

The first paper read was by Dr D E Salmon, Chief of the Bureau of Animal Industry, entitled,

TUBERCULOSIS AND THE FOOD SUPPLY

The author assumed without argument, as already established by scientific investigation, that tuberculosis is a parasitic disease, that it is caused by the multiplication of a specific microorganism in the tissues of the animal body and by no other means Of the two methods by which the disease is contracted, with man as well as with animals, it may be admitted that the most frequent and therefore the most important is the inhalation of the microorganisms suspended in the inspired air The speaker had no means of estimating the proportion of cases of tuberculosis which arise from infected food, but he was prepared to admit that tuberculosis of the abdominal organs and tubercular meningitis, particularly of children, were generally caused in this way The author then considered infection through the milk supply and infection through the meat supply Tuberculosis is one of the most common diseases of milch cows It exists in many dairies, and may affect 50, 75 or 100 per cent of the animals in large herds We do not know the average proportion of cows affected in this country, but in the dairies around our large cities from 3 to 5 per cent have been affected when the diagnosis was made by the ordinary methods of examination In the United States we have no statistics of the results of the tuberculin test, except with herds known to be tuberculous Fortunately the milk from all tuberculous cows does not contain the bacilli When there are tubercles in the udder, however, the milk may contain immense numbers of these germs, and this is particularly the case if the tubercular mass softens and its contents escape into the milk ducts The milk from cows so affected must be considered an extremely dangerous article of food

The prevalence of tuberculosis in dairy cows can be lessened, and the danger from infected milk diminished, by a careful and periodical inspection of the herds from which the milk supply is obtained This inspection must consist not only of a physical examination, but must also include the tuberculin test There must in addition be some means provided for securing the destruction of animals found to be tuberculous

SYPHILITIC INFECTION AS A VEHICLE OF THE COMMUNICATION OF TUBERCULOSIS

By Dr Manuel Carmona y Valle of Mexico The author of this paper cited the history of a case demonstrating the possible association of the syphilitic virus with the pathogenic agent of tuberculosis and the possibility of transmission not only of the syphilis but of the tuberculosis also He had found in the ulceration of the throat both characters

THE INFLUENCE OF HABITATIONS IN THE PROPAGATION OF TUBERCULOSIS

By Dr Manuel Gutierrez of Mexico Pulmonary tuberculosis is more frequently observed in the United States than in the Republic of Mexico The statistical records give a proportion of from 118 to 120 per thousand in America while in sunny Mexico it does not reach the number of 60 to every thousand One of the causes which contribute to produce so notable a difference in the propagation of so dangerous a disease, is the difference of the elevation in both countries, because we know that dry air is not a vehicle for the multiplication and generation of the bacillus of Koch, and the relative rarefaction of the air is in a direct ratio to the elevation Mexico being 2,257 meters above the sea level, it is consequently not difficult to explain its superiority in arresting the conditions favorable to the propagation of a disease which undermines so many constitutions

The author's attention has been called to the fact that not only in the hotels, and public establishments, but also in private dwellings in the United States, there are rooms constantly illuminated with artificial light and in which the light of the sun never penetrates The individuals who work therein are deprived for many hours of the beneficial action on the economy that we know solar light exerts, and we know that these privations and the special conditions that accompany it can contribute to the development of tuberculosis by producing 1 the anemia and its consequent state of malnutrition, preparing the ground that serves for the cultivation of the germs of the disease, 2, increasing considerably the temperature of the place illuminated, constitutes also a propitious cause of multiplication of the pathogenic principles involved and in the tubercular process

PROPHYLACTIC AND THERAPEUTIC VALUE OF FOOD

This paper was contributed by Mrs Ellen H Richards of Boston She said the prophylactic value of food is to keep the human body in a high condition of health The main object to be gained is to establish a higher standard of health in the community, to make as widely known as possible the fact that most of the ill health now prevalent is needless, that a little self-denial, a little more attention to the rules of hygiene, a little more living in the open air would cause a large number of the diseases now so common to disappear

HYGIENE OF HAIR DRESSING AND BARBER SHOPS

By Dr Angel Contreras, Pueblo, Mexico The disease which persons are most liable to contract in barber shops is scurf, and the author therefore touched on what appeared to him the most important points in the consideration of this matter Scurf is understood to be a disease of the capillary system caused by the presence of vegetable parasites The disease can be transmitted by some animals which already have it, but the contagion most commonly takes place from person to person, and in families in educational establishments and in barracks, the disease assumes an endemic character Several times the center of this propagation has been found in a hair dresser's or barber's shop, and has arisen from the use of instruments which have been badly cleansed Barbers and hairdressers ought therefore to be very careful in cleansing the utensils which have served for one person before they are employed on another All the utensils should be subjected to the action of heat for a space of ten minutes, in a vessel or receptacle at a temperature of 120 degrees, and the razors in an oil bath

THE WATER SUPPLY OF CHICAGO, ITS SOURCES AND SANITARY ASPECTS

By Arthur R Reynolds, M D, Commissioner of Health of Chicago, and Mr Allen Hazen The extensions of the various tunnels within the last two years have undoubtedly secured for the city a water less liable to sewerage pollution than was formerly obtained The available analyses of the water are perhaps inadequate to measure accurately the improvement but fortunately we can apply that most satisfactory of all tests, the typhoid fever death rate The improvements in the water intakes have not all been made at a single date, but if we compare the two years ending September, 1892, and Sept 30, 1893, we find that during the earlier years the shore intakes at Lake View and Chicago Avenue were in common use while the four mile tunnel was not yet opened, while for the greater part of the latter year the shore inlets were entirely closed and the four mile tunnel and the one mile tunnel at Lake View were in use For the year ending Sept 30, 1892, the number of deaths from typhoid fever in Chicago was 1,790 in a total of 26,646, or a percentage of 6 72 For the year ending Sept 30, 1893, the deaths from typhoid fever were 712 in a total of 26,977, or a percentage of 2 64 It is most unfortunate for this comparison that the old supplies were partly in use during the first four months of the latter year, before the four mile tunnel was opened We may believe that if this had not been the case the comparison would have been still more favorable to the improved supply

It is a well-known fact that people using a water supply to which they are not accustomed are often more susceptible to any infection which it may contain than are those using such water regularly A striking illustration was furnished by Philadelphia in the Centennial year, when the typhoid death rate was nearly doubled, while in Chicago the present year for the first five months of the Fair period the rate has been less than half as high as for the corresponding months of the preceding year, and for the entire year under consideration, in spite of the vast numbers of visitors continually present, there has been a reduction of over 60 per cent in the typhoid fever death rate This reduction is most striking, and it can hardly be doubted that the improvements in the water supply have been the chief, if not the only cause As there is no marked local distribution of the typhoid fever, so there were no exceptions to the general improvement with better water supply Not a single ward but showed a substantial reduction Stronger evidence could hardly be produced to show the causal relation between the contamination of the water supply and typhoid fever The mortality percentages from typhoid fever in a number of cities may be compared as follows Chicago, 1892, 6 72, in 1893, 2 64, Philadelphia, 1892, 2 22, Boston, 1 22, Paris, 1 01, New York, 90, Brooklyn, 80, London, 49, Berlin, 42 The cities having the lowest typhoid fever death rate, London and Berlin, use only filtered water London draws nearly all of its water from the two grossly polluted rivers the Thames and the Lea and, after filtering it, applies it to a population that is almost free from typhoid fever It may be a question worthy of consideration by the engineers whether filtration would not be as cheap and effective a means of improving the water supply as the farther extension of the tunnels

REMOVAL OF PATHOGENIC BACTERIA FROM DRINKING WATER BY SAND INFILTRATION

This paper was read by Mr George W Fuller of Lawrence, Mass That drinking water is a carrier of some diseases there can be no doubt Numerous laboratory experiments by many investigators indicate that the bacteria generally attributed to be the specific organism of typhoid fever, Asiatic cholera and other diseases live in ordinary drinking water for many days The results of long-continued investigations at the Lawrence Experiment Station, show that the typhoid bacillus is able to live in the water of the Merrimac River, in greatly diminished numbers, for a period of at least twenty four days Other investigators using different water and different conditions, estimate the length of life of this germ at from three to eighty days The duration of life of the cholera spirillum in various waters has been observed to be from two days to seven months Modern hygiene demands that drinking water shall be free from pathogenic bacteria, and the means by which such water can be obtained are worthy of our most careful consideration

During the past forty years many filter plants have been constructed in Europe and numerous experiments in the filtration of water have been made, particularly during the past decade This is largely due to the aid of bacteriology which enables us to determine the actual efficiency of filters with regard to the removal of bacteria The operation of many filters is quite satisfactory, as is shown by the low death ratio from these diseases, conveyed by drinking water and by the results of numerous bacterial analyses

In summing up our present knowledge upon the removal of pathogenic bacteria from drinking water, we may state that in addition to the experience of certain European cities, the Lawrence investigations covering a period of more than five years, and including the bacterial examination of more than eleven thousand samples of water indicate that it is entirely practicable to construct filters that will economically purify water and remove more than 99 per cent of bacteria which may be present in the unfiltered water

"The Potable Waters of the Country Presenting Many Dangers" This paper was read by Dr Thomas Noriega of Mexico "Statement of Scientific and Experimental Data for the Establishment of International Maritime Police," was read by Dr E Liceaga of Mexico Dr Domingo Orvanaños of Mexico, read a paper entitled, "Difficulties in the Practice of Quarantine in Some of the Mexican Ports" Other papers were read as follows on this subject "The Canadian Quarantine System" by Dr Frederick Montizambert of Quebec, Canada, "Quarantine System of Texas," by Dr R M Swearingen of Texas, and "Quarantine," by Dr S B Olliphant, President of the Louisiana State Board of Health

Evening Session

At this session, addresses were delivered by Dr Sarah Hackett Stevenson of Chicago, on "Municipal Sanitation," by Miss Ada Sweet of Chicago, on "Voluntary Health and Public Improvement Societies," a paper by Sir Charles Cameron of Dublin, on "Importance of Civic Public Hygiene to the State," "Municipal Sanitation of Minneapolis," by Dr E S Kelly, of Minneapolis, and "The Importance of Sanitary Bureaus, Their Economic Organization," by Dr Jesus E Monjaras, Sanitary Inspector of San Luis Potosi, Mexico

October 13—Fourth Day—Morning Session

Papers were read at this session as follows "The Best Way to Restore the Practice of Vaccination to Its Proper Place as a Preventive of Smallpox," by Dr Charles N Hewitt, Secretary of the Minnesota State Board of Health, "Animal Vaccine Why It Should be Preferred to Human Vaccine" by Dr Miguel Marques of Chihuahua, Mexico; "La Grippe," by Dr Gregorio Mendizabal of Mexico, "Diphtheria in the City of Mexico," by Dr Roque Macouzer of Mexico, "Notes on Scarlet Fever in the City of Mexico," by Dr Francisco Marin of Pueblo, Mexico, and "Unrest," by Dr William Oldright of Toronto

AN EXPERIMENT IN DISINFECTION—HOW AN EPIDEMIC OF PNEUMONIA WAS CHECKED

This was the title of a paper read by Dr Jerome Cochran of Montgomery, Ala The paper dealt with an epidemic of pneumonia checked by disinfection The total number of cases during the epidemic was ninety-three, total number of deaths thirty, nearly one third of the cases The epidemic occurred in the prison at Pratt Mines, Alabama. The prison was divided into three sections, and while the disinfection was going on in one section the convicts belonging to that section were crowded into the other two sections The mattresses were taken off, and these together with the blankets were scattered over the floor Then by means of a force pump and a long hose pipe the ceilings, walls and the floors with their contents were literally deluged with a solution of bichlorid of mercury, 1-1000, until the bichlorid solution stood in puddles and ran in rivulets on the floors The mattresses were turned over so as to be wetted as thoroughly as possible on both sides Dr Cochran has more confidence in the disinfecting power of heat than in the bichlorid The mattresses, blankets, etc, were therefore put into large steam chambers that had been constructed for the purpose and kept there for six hours, after which they were taken out and dried In the meantime the disinfected wards were thoroughly scrubbed out whitewashed and fitted up so that they could be occupied again the next day The convicts, before they were returned to their old quarters, were required to take a bath and to put on clean clothes In one week the epidemic attacked at the period of its most rapid increase, went out like a fire under a deluge of water

A CONTRIBUTION TO THE STUDY OF YELLOW FEVER FROM A MEDICO GEOGRAPHICAL AND PROPHYLACTIC POINT OF VIEW IN THE MEXICAN REPUBLIC

This paper was read by Dr E Liceaga, President of the Superior Board of Health, Mexico The author presented the following conclusions

1 The places where yellow fever reigns and which can be considered as centers of infection are in the Gulf of Mexico, Vera Cruz, Frontera, Campeche and the districts on the northern coast of the Yucatan Peninsula, the last named separated by the Yucatan canal from the island of Cuba, where the fever also reigns On the great Pacific Coast, which belongs to the Mexican Republic, there is not a single yellow fever center

2 All the Mexican territory on the Gulf of Mexico and on the Pacific Coast is well adapted for the disease when imported

3 Yellow fever has become epidemic in the following places of the coast on the gulf Matamoros, Altamira, Tampico, Tuxpam, Papantla, Misantla, Nautla, Alvarado, Goarzavoalcos Minatitlan Lagang and San Juan Baptista de Tabasco

4 The epidemic has extended into the interior, but never into places situated more than 1,008 meters over sea level

5 On the Pacific *there is not* a yellow fever center, but it has been imported into the following places on the peninsula of Lower California, La Paz y Todos Santos, *on the* continent, Guaymas, Altata, San Blas, Mansanillo, Santiago, Acaponeta, Puerto Angel, Salina Cruz, Tonala Soconuzco Tapachula and San Benito, and in the interior in Hermosillo y Culiacan

6 Immunity against yellow fever is obtained after having had the disease in any of its forms It is possible that this immunity may be lost at times, but it is seldom the case, as

it happens with typhus, smallpox and scarlet fever, which may be had by a person who has had them

7 The vaccine of Jenner against smallpox, and others which science has discovered, authorize us to look for the one that will prevent the yellow fever The inoculations against this fever which Dr Manuel Caramona y Valle has practiced with success should be tried on a large scale, in a uniform manner, in order to be able to find out if they are efficacious If this experience confirm it, then they should be made compulsory in the countries where the fever reigns If they should not prove worthy, then the inoculation of blood serum as proposed by Dr Sternberg, from persons enjoying immunity, should be tried on a large scale and in a uniform manner

8 The purification of the drinking waters, used by persons who have to expose themselves to contract the disease, should be recommended The purification of the water used on board the ships leaving or calling at infected ports should be proposed

9 The sanitation of the places which are yellow fever centers should be done at once

10 To prevent, by means of sanitary police measures, the importation of fever into places where it can be developed

HOW SHALL OUR LEPERS BE CARED FOR?

Was read by Dr Benjamin Lee of Philadelphia, Pa He said the State Board of Health of Pennsylvania, and the Board of Health of the city of Philadelphia, have had some unpleasant experiences with lepers which had led both of these bodies to appeal to the general government to establish a colony or colonies where these unfortunates might be provided with the comforts of home and medical care and nursing and at the same time might cease to be a menace to the health of those with whom they were thrown in close contact The United States had only gone so far as to make the affection quarrantinable at the seacoast and to order those found suffering from it on arriving vessels to be at once returned to the ports from which they came

Dr Manuel Carmona y Valle of Mexico, contributed a paper on "Yellow Fever" Papers were also read by Dr Luis E Ruiz of Mexico, on "Typhoid Fever in the City of Mexico," "Some Reflections on the Infection and Contagion of Typhus Exanthematicus," by Dr Ramon Icaza of Mexico, "Registration," by Dr S W Abbott Wakefield Mass

Dr John H Rauch of Chicago Ill, introduced a resolution to suspend immigration until the pandemic of cholera in Europe was over which, after some discussion, was referred to the Executive Committee

The American Public Health Association elected the following officers

President—Dr E P La Chapelle of Montreal

First Vice-President—Dr Manuel Carmona y Valle of Mexico City

Second Vice-President—Dr J N McCormack of Bowling Green Ky

Treasurer—Dr Henry D Holton of Brattleboro Vt

Permanent Secretary—Dr Irving A Watson of Concord, N H

Place of next meeting—Montreal, Canada October, 1894

Note —Although the gathering was denominated an International Congress of Public Health, very few outside of the members of the American Public Health Association contributed to the proceedings The bulk of the work was done by the members of the American Public Health Association

After drafting introducing and adopting resolutions of thanks, the President declared the Congress adjourned

---

New York County Medical Association —The first meeting of the New York County Medical Association after the summer vacation, was held on the evening of October 16, when Dr Edward G Janeway, who was until recently a Commissioner of the Board of Health, read a paper on "Dangers to the Public Health from Overcrowding Population" The discussion on it was opened by Dr Charles A Leale ex-president of the Association, who is especially familiar with this subject on account of his labors in connection with St John's Guild which every year treats so many thousands of the children of the tenement houses on its floating hospital excursions and at its seaside hospital on Staten Island Among others who took part in the discussion were Drs J R MacGregor, also an ex-president of the Association, and J Lewis Smith, the veteran authority on diseases of children A second paper was read by Dr Frank Van Fleet, on "The Necessity of Perfect Vision in the Education of the Young"

The County Association is in a most flourishing condition, as evidenced by the handsome register of members and manual of information just issued by it, which shows an active membership of no less than 920, as against 805 at the same time last year Besides the annual report of the Association, the work referred to contains the decision of the American Medical Association in regard to membership, and report of committee of conference in the interest of harmony in the State of New York, the report of the committee in regard to the revision of the Code of Ethics and By-laws of the National Association, lists of all the presidents of the New York State and American Medical Association, the present officers, and articles on the medical profession and the Columbian Exhibition the International Medical Congress and the Pan American Medical Congress

C, M & St P Railway Surgical Association —The first meeting of the surgeons of this road was held in room 536, Rand-McNally Building, Chicago, Oct 4 and 5, 1893

The meeting was called to order by Dr A D Bouffleur, the surgeon of the road at Chicago, who in a brief address of welcome, outlined the objects of the Association and the work of the session

Dr Solon Marks of Milwaukee, was elected chairman for the meeting Dr A J Bouffleur was elected permanent secretary, subject to the approval of the management of the company, which concurred in the selection

The following papers were presented

Injuries of the Head, Dr H B Hemenway

Shock in Railway Injuries, Dr L A Squire

Leading Indications for Treatment in Severe Injuries of the Extremities, Dr J A Jackson

Treatment of Contused and Lacerated Wounds, Dr Wm. Mackie

Importance of Controlling Hemorrhage after Railway Injuries, Dr Ira K Gardner

Antisepsis Simplified, Dr M S Caldwell

First Aid to the Injured by Trainmen, Dr A B Poore

Injuries to and About the Eye, Dr C D Westcott

Sacro iliac Dislocation, with a Case, Dr N M Dodson

Antiseptic Uses of Potassium Permanganate, Dr A L. Clark

Special Ethics of Railway Surgeons, Dr Geo R Moore

Technique of Amputations, Dr G D Ladd

A Case in Practice, Dr O W Phelps

A Case in Practice, Dr N A Drake

Each paper was thoroughly discussed As there were one hundred and thirty surgeons present, the meeting was both a numerical and a scientific success

President Roswell Miller addressed the Association on the relations of the surgeons to the management, and assured them of his hearty cooperation in all their efforts

The future management of the Association was consigned to Dr Bouffleur, the secretary, and an executive committee consisting of Drs A B Poore Wm Mackie and B Thompson

Pennsylvania Railway Surgeons —The Twelfth Annual Meeting of the Association of Surgeons of the Pennsylvania Company was held at the Seventh Avenue Hotel, Pittsburg, Oct 10 Members were present from all divisions of the system, and a large number were unable to reach the meeting on account of a railway accident In the absence of President J J Larkin of South Chicago, Dr Mont Linville of New Castle, presided

An interesting paper was read by Dr C B Stemen of Fort Wayne, on "Antiseptic Precautions in the Treatment of Railway Injuries," which was discussed at considerable length by the members present A number of other papers were to have been read, but were dropped from the program an account of the inability of the authors to be present Considerable business of a routine nature was transacted and the following officers were elected for the coming year Dr Mont Linville, New Castle President, Dr J B Vail, Lima, First Vice-President, Dr E J McCollum, Tiffin, Second Vice-President, Dr George C Stemen, Fort Wayne, Secretary and Treasurer, Dr H Nye, Enon, Pa, Dr L C Botkin, Burgettstown, and Dr S A Craig, Freedom, Executive Committee

The next meeting of the Association will be held in Chicago in October, 1894

The Railway Surgeons —The first annual convention of the Ohio Association of Railway Surgeons met at the Forest City House, Cleveland, October 12 President S S Thorne called the convention to order with twenty-five delegates present

American Public Health Association —The following officers were elected for the ensuing year Dr Emanuel P La Chapelle, President, Montreal Dr M Carmona y Valle of Mexico, First Vice-President, Dr J N McCormack of Bowling Green, Ky, Second Vice-President, Dr Henry D Holton, Brattleboro, Vt, Treasurer, Dr Irving A Watson, Concord, N H, Secretary Place of meeting Montreal, October, 1894

Medical Journal Publishers' Association —An organization was perfected at Hotel Willard, Washington, September 8 and elected the following officers President, Dr L B Edwards, *Virginia Medical Monthly,* Vice-President, Dr J C Culbertson, *Lancet-Clinic,* Secretary, Dr F King, *Polyclinic,* Treasurer, J MacDonald, Jr, *International Journal of Surgery,* Executive Committee Drs Stowell, LeGrand, Fairchild, Fassett and Chambers Next meeting at Cincinnati, in December

The West Tennessee Medical and Surgical Association will be held at Brownsville, Tenn, October 26 and 27 Dr J R Hillsman of Trezevant is President, and Dr F L Sim, the editor of the *Memphis Medical Monthly,* is Chairman of the Committee on Publication

The Northwestern Wisconsin Medical Association, held their quarterly meeting October 10 at Stevens Point, Wis

The Oneida County, N Y Medical Society held its semi-annual meeting at Rome, N Y, October 10

NECROLOGY

Dr H A Youmans, an old settler and highly respected physician, died at the home of his son in Waukesha, Wis, October 4

Dr Walter G Stebbins, died at Boston, Mass, October 8 of diphtheria

Dr Wm Fitch of Dryden, N Y, died September 14 He was graduated from Albany Medical College in 1846

Dr Clarence Andrews of Kansas City, Mo, at Adrian, Mich October 14

Dr Francis J Chamberlayne, at San Diego, Cal, aged 77, October 5

Dr Joseph VanDyke, at Charleston, Ill, October 12

Dr Benjamin Norton of Hornellsville, N Y, October 3

Dr L P Dodge of Farmington, Minn, died September 29

Dr T H Gibbey at Manchester, N H, October 16

Dr Emil Guelich, at Alton, Ill, October 15

Dr Richard A Matthews, athlete and physician, died of stomach trouble October 14, at the age of 28 years He was for two years a member of the *Evening World's* Corps of Physicians for the Sick Babies, and was also the surgeon for the Columbian line of steamships, which runs between New York and Colon Dr Matthews was born in this city and graduated from the New York University He began to practice medicine in 1891 He was a member of the old Manhattan Athletic Club, and played in its football team in 1887 He was a member of the Staten Island Athletic Club, and played in the lacrosse team He also rowed in the junior eight-oared crew of that club —*New York World*

MISCELLANY

The Cholera in Hamburg —Quarantine, S I, Oct 4, 1863 Dr Nash has lately written the following

To the Editor of the Times Democrat

'Having just arrived in New York on the 'Augusta Victoria' from the city of Hamburg I consider it my duty to state publicly the result of my observations while on my post there

"I have been stationed in Hamburg since Jan 6, 1893, as the representative of Dr Jenkins, health officer of the port of New York, and I think that during that time, with the opportunities at my command, I have been able to inform myself thoroughly as to the actual sanitary condition of the city, the ways of the authorities, and the interests which stand in so close a relationship with America, and I feel bound to contradict the unfair criticisms which have been passed upon the city, and correct the false impressions which have gone abroad as to the conditions prevailing there

"During the whole of the present year the health of Hamburg has been excellent, the average mortality being far below that of the principal cities of the world The cleanliness of the streets is exemplary, they are swept and scraped and washed until they almost shine again, the blind alleys and courts are also well looked after The street brigades are uniformed, and handle their implements in an expert manner The markets in the different sections of the city are models of neatness At the close of business hours each day every scrap of refuse and garbage is at once removed under the supervision of the sanitary police corps

'On my arrival the city was as yet unsupplied with filtered water, but now and since several months the city enjoys the boon of a pure filtered, germ-free water in abundance for all purposes I can hardly say enough in praise of the city and its authorities for the thoroughly scientific manner, the tireless energy and disregard of expense with which the enormous plant supplying the city with pure water has been established in the short time At ebb tide the water is led into immense basins, where it is filtered through different strata of sand pipes Bacteriological examinations repeatedly made of this filtered water have all testified to its purity, and its universal use has given additional proof of it

"An unfortunate accident occurred on the 16th of last month, by which unfiltered water obtained entrance into the service mains This accident was due to giving way of the earth, and was immediately repaired but the consequence of the contamination became apparent A few sporadic cases of cholera occurred, which, however spread alarm only in places far distant from the city, where the news was used to injure Hamburg, as had been done repeatedly on former occasions In the city there was no alarm, the people felt their security and confided in the efficiency of their sanitary authorities The result has warranted the expectation Altogether only a small number of cases occurred, mostly of a mild type, and the latest news shows that even these have disappeared The city will now doubtless return to its remarkable good health record, which, even during the hottest part of the year, was an extraordinary one

"Tourists and travelers to and from the European continent can not do better than choose the route via Hamburg on account of the superior sanitary conditions of the city as well as for its other attractions For Hamburg is a magnificent place To see the beautiful Alster Basins, surrounded by pretty parks and fine avenues, lined with handsome buildings and villas, is alone well worth a journey Good hotels, excellent restaurants, amusements to suit every taste, clean streets and the activity of life and business of a great commercial port, and other points to be considered

"A few words now regarding the Hamburg-American Packet Company

"This company has complied readily and thoroughly with the measures required by Dr J H White, the representative of the United States Marine Hospital Service, stationed in Hamburg, and also with whatever recommendations have been made by myself, as representing the New York State Quarantine Suggestions, of whatever nature, have been gladly received, and cheerful and ready help has been given to both of us in our work The disinfection of ships and baggage, the supervision and scrutiny of passengers and other measures tending to the welfare of all concerned are done under our control and, in my opinion, no steamships leave any port in more complete sanitary condition than do the steamers of this company Dr Jenkins has repeatedly made the same statement regarding the same steamers arriving in New York

"The company has also, of its own accord, frequently adopted precautionary measures of considerable importance and at great cost, solely for the purpose of guarding against the possibility of any danger

"As an American residing in Hamburg, and as an official I testify to the conditions as outlined above, and gladly bear witness to the sincerity of the intentions of the city authorities and of the great corporations located there, and if I ask you to publish this letter it is with full reliance on the American spirit of fair dealing, and with the hope that my statement may tend to remove unjust reflections I am, dear sir, yours very truly, DR GEORGE W NASH,

Representing New York State Quarantine at Hamburg

To Admit the Physicians—Opening of Health Department Hospitals to them to be considered to day The details of the plan to open the Health Department hospitals for contagious diseases, to the medical profession for the mutual benefit of the profession and the department, will be laid before the Board of Health this afternoon by President Wilson The plan is simple it proposes the appointment of six attending physicians, whose duty it shall be to visit the hospitals twice a week at any rate They may, if they choose, visit every day and at all hours

Besides these, a fixed number of internes will be assigned to the hospitals who shall act as assistant resident physicians and hold their places for six months each This is the system adopted in other hospitals the world over The internes will be graduates of the medical schools Their appointment amounts to the establishment of a post-graduate course, which will speedily become exceedingly popular

The attending physicians will be chosen from among the professors and experts of the four medical colleges in the city They will be chosen for their conspicuous ability and prominence as practitioners, and upon them will devolve a great share of the responsibility for the management of the hospitals As lecturers at the colleges they will be allowed to take their classes with them on their visits to the island, under the restrictions of the Department as to dress and disinfection Thus clinics will be set running in the most natural way—not once or twice a week, but probably every day,

Physicians and internes will be unsalaried, but the latter will live in the hospitals to which they are attached It is expected that the plan will be promptly adopted and the scheme, as here outlined carried out at once It is likely even that the staff of attending physicians may be chosen and invited to accept Nothing that has happened in the history of the department has claimed and received such hearty support on the part of the medical profession *The Evening Sun's* announcement yesterday of the impending opening of the hospitals aroused the interest of the doctors thoroughly It was the one topic of discussion among them yesterday Without an exception, they indorsed the new departure of the Health Department as the most intelligent and most promising move made by it in recent years—*New York Evening Sun*, Oct 11, 1893

The Illinois Board of Health—The Illinois State Board of Health has issued a circular on the necessity for public vaccination, and says

"Indications are now multiplying, which point to a general epidemic spread of the disease throughout the whole country as cold weather approaches Introductions of the contagion will thus grow more frequent and, sooner or later, are likely to find any unprotected community and there establish an outbreak The State Board of Health urges upon you the necessity of preparation while there is yet time—during the remaining weeks of pleasant autumn weather Vaccination of all unprotected and revaccination of all those vaccinated within the past few years should be secured without delay

"The State Board of Health enjoins upon all local health authorities the urgent necessity of measures to secure the vaccinal protection of all over whom they have control Local ordinances—if not already enacted—should be passed forthwith, enforcing vaccination or revaccination upon all school children, public, private and parochial, upon school teachers, janitors and others, upon all public employes and officials, through all employers of labor, skilled and unskilled, upon their employes as a condition of further employment, through superintendents of public and semi-public institutions, upon every inmate, employe and official of such institutions, all tramps, and especially upon immigrants from abroad The Board will lend every assistance in its power to secure the end in view and invites correspondence on the subject, to be addressed to the secretary

"By order of the Board JOHN W SCOTT, M D,

"*Secretary*"

The First Professional Organization—Norwich Doctors Wanted a Medical Practice Act in 1774—The medical practice act suggests the historical fact that the first step toward professional organization and protection in Connecticut was taken by Norwich physicians on the 3d of March, 1774 On that date the following advertisement appeared in reference to the project

"A number of Physicians in the County of New London, taking into consideration the importance of those that enter the practice of Physick being endued with competent knowledge to prosecute the undertaking in such a manner as shall best promote the public good, request their brethren of the Faculty in said County to meet at the house of Mr Azariah Lathrop, in Norwich, on Thursday the 24th inst, at 10 o'clock in the forenoon, to consider upon the matter and prefer a Memorial to the General Assembly at their next Session, that the Practice of Physick may be put under some better regulation"

This memorial, which was signed by Theophilus Rogers and ten other physicians, was the first movement toward medical organization in Connecticut "Quacks and charlatans" had disgusted the regular physicians, and their demand was for the appointment of a committee legally authorized to examine and approve candidates, if found qualified The movement, which was in advance of the age, was negatived in the lower house, but the memorialists were the pioneers in the cause of American medical organization, and their unsuccessful first attempt was the initiative step in a series of efforts which have since resulted in the permanent establishment of flourishing State and National Associations, which separate the qualified physician from "the ignorant pretender"—*Norwich* (Conn) *Bulletin*, Oct 9, 1893

Yellow fever continues its ravages at Brunswick, Ga, from twenty-five to thirty new cases appearing daily A despatch from Brunswick on Monday stated that supplies of food were being received very slowly and that unless large contributions were quickly made there would be great suffering among the people

Report of Muncie Smallpox Cases—The report of the Muncie smallpox cases has been submitted to the Governor It shows that since the disease first appeared there the number of cases has been 136 Fourteen cases are now under treatment at homes and the hospital Thirty-nine convalescents are reported The same number are well, but have not been discharged Thirty-one cases have been cured There have been sixteen fatal cases Last week $1,000 was appropriated from the State epidemic fund to aid in suppressing the disease The Governor will decide to day how much will be allowed for the next seven days The cases are being concentrated at the hospital, and it is thought that not so much money will be needed —*Indianapolis News*, Oct 13, 1893

A Professional Beautifier —A certain Dr Robert Fisher a professional beautifier of Vienna, has been revealing the secrets of the trade He declares that many mothers put their daughters through a whole course of beautification before marriage The doctor divides his treatment into the negative and the positive By means of the first method he removes blemishes that exist and by the latter he improves the good points that nature has already given the subject He has even gone so far as to invent a "tear pump," designed to aid in the timely display of emotion —*N Y Sunday Mercury*

Looking for a Hospital Site —Drs William H Ford, E O Shakespeare and William Welsh, who were appointed several months ago by the Mayor to select a site for a new municipal hospital, with that object in view, have visited several places in outlying districts The present hospital location, it is said, retards the progress of building operations in the northern section of the city, while the proceeds to be obtained by a sale of the property with its large grounds would be ample to secure far better accommodations for the treatment of contagious and infectious diseases —*Philadelphia Public Ledger*

N Y Pasteur Institute —The commodious new building of the New York Pasteur Institute, which is beautifully situated in Central Park, at the corner of 97th Street, was opened with appropriate ceremonies on October 9th Addresses were delivered by Dr Paul Gibier, the Director of the Institute, by Prof R Ogden Doremas, and by Vicomte d'Alzac, Consul General of France, after which a collation was served

The Mayor did not Approve —The authorities of the city of New Haven rejected the recommendation of the Board of Health for the establishment of a contagious disease hospital The mayor is reported by the *New Haven News* of October 11, as saying he preferred to have the general hospital take care of these cases! Sapient Mayor!

Infant's Hospital —An infants' hospital is to be established at Athol Springs, thirteen miles from Buffalo, by the "Fresh Air Mission" of that city Dr Eugene Smith of Detroit, has sold to the Mission the Athol Springs Hotel and the Spring House The hospital is intended to be used in the summer only

Punished for a Wrong Diagnosis—The Chinese Way —Four members of the Imperial College of Physicians at Pekin, who failed to give a proper diagnosis of the Emperor's recent indisposition, were punished by having a year's salary taken away from them

Legacy to Philadelphia Hospitals —The Ingersoll estate was partially divided, October 11, by which the Episcopal Hospital, the Children's Hospital and the Consumptives Home, all of Philadelphia, each received one-third of $476,574,67, the residue on hand at the date of the distribution

Suffering at Brunswick —Great suffering prevails at Brunswick, Ga, on account of the yellow fever epidemic, and the inhabitants have appealed for relief Many supplies hav[illegible] been sent, but there is still greater need of supplies tha[illegible] ever It is not likely that the situation will improve unti[illegible] after frost

Dr Harry B Favill of Madison, Wis, has accepted the chair of general medicine in the Chicago Policlinic He will still live in Madison as but one half his time will be needed in his college work

Won his Case —Dr J E Reeves of Chattanooga, who was sued for damages by the "Amick Consumption Cure" Company, for denouncing the concern as fraudulent, won his case in court

He Failed to Notify the Board of Health —Dr Leander A Cliffe of Roxbury district, Boston, was arrested and found guilty of violation of law for failure to report a case of diphtheria

Sanitarian Injured —Dr Lewis Balch, Secretary of the State Board of New York, received a painful injury by being thrown from a horse near Albany on the 7th instant

Emergency Hospital —An emergency hospital was dedicated with appropriate ceremonies, at Nashua, N H, October 1[illegible]

A New Hospital was opened at Little Falls, N Y, on October 16 by the Hospital Association of that city,

Dr R Harvey Reed of Mansfield, O, has been appointed consulting surgeon to the "Big Four" railroad

The New Hospital Building at the Soldiers' Home, Milwaukee, has just been completed

A Hospital for contagious diseases has just been completed at Spokane, Washington

THE PUBLIC SERVICES

Army Changes Official list of changes in the stations and duties of officers serving in the Medical Department U S Army, from October 7, 1893 to October 13 1893

First Lieut George D De Shon Asst Surgeon is relieved from further duty pertaining to the medical section of the War Department Exhibit World s Columbian Exposition, Chicago, Ill and will return to his proper station Ft D A Russell, Wyo

First Lieut Allen M Smith Asst Surgeon, will proceed without delay to Ft Missoula Mont and report to the commanding officer of the post for temporary duty to enable Capt William D Crosby Asst Surgeon to take advantage of the leave of absence granted him

Capt George McCreery, Asst Surgeon U S A (Ft Sidney Neb) granted leave of absence for one month, to take effect about Oct 15 1893

Navy Changes Changes in the Medical Corps of the U S Navy for the week ending October 14 1893

Medical Inspector George H Cooke from Navy Yard, League Island, Pa and to special duty in Philadelphia, Pa

Surgeon E Z Derr ordered to Navy Yard League Island, Pa

Surgeon B S Mackie, detached from duty in Philadelphia, Pa and wait orders

The Journal of the
American Medical Association

VOL XXI CHICAGO, OCTOBER 28, 1893 No 18

ORIGINAL ARTICLES

THE ORIGIN OF GLAUCOMA AND A SUGGESTION AS TO ITS EARLY MANAGEMENT

Read in the Section on Ophthalmology at the Forty fourth Annual Meeting of the American Medical Association

BY LOUIS F LOVE, M D
OPHTHALMIC SURGEON TO ST MARY'S HOSPITAL, ETC
PHILADELPHIA PA

I do not desire to present any novel ideas with regard to the origin of glaucoma, or to recommend any special treatment of its earlier manifestations My object is rather to direct attention to what I believe to be the principal cause of glaucoma simplex and acute inflammatory glaucoma, and to suggest the use of well known remedies for a condition which may prove the starting point of the disease The nature of this obscure trouble has always been a subject for speculation, from the earliest days of medicine, but it is only comparatively recently that its pathological character was understood The work of the anatomist, the physiologist, the pathologist and the clinician have shed much light upon what was obscure to the older physicians Until the time of von Graefe the character of glaucoma was very obscure, his discovery of its general character was a very great step forward, but left unexplained how or why the increase in intra ocular pressure was caused The circulation in the eye, and the nature of the ciliary body were then not understood but von Graefe was shrewd enough to refer the cause of the pressure to a disturbance of the circulation When the anatomist and physiologist had made clear the wonderful method by which the nutrition of the structures of the globe is maintained and had proved the existence of a current from the ciliary body through Schlemm's canal and into the triangular space, it was seen how obstructions of these small channels might readily cause such a disturbance in secretion and excretion as might cause an increase of intra ocular pressure and thus the symptoms of glaucoma and, if maintained, the disease itself (*Knies and Weber*)

Any cause which produces a rise in the intra ocular pressure will give rise to some, at least, of the common symptoms of glaucoma They may be produced temporarily in the normal eye by a simple practice that I have often adopted If the head of a subject possessing normal eyes is held in a dependent position and at the same time pressure is made on the eyeball for a short time, the subjective symptoms produced will be similar to those of disease The globe becomes tense to the trained touch, chromatic rings surround a bright point of light and these symptoms accompanied by severe pain, if the experiment is carried far enough, and occasionally ciliary neuralgias are produced These symptoms are evidently due to a disturbed circulation, and the study of the pathological conditions existing in glaucoma has confirmed the reasoning of the anatomist and physiologist The cupped disc shows the effect of the intra-ocular pressure and where inflammatory processes have been set up their effects are found in the ciliary region The cause of the increased intra-ocular pressure has therefore been justly assumed to be a disturbance in the fluid circulation of the eye *But what should cause a disturbance in a body* so remote from external influence as the ciliary body? To this question no entirely satisfactory answer has yet been made, and I would therefore suggest that a further inquiry be made to determine the more remote causes of these changes in the circulation It is very well known that the blood circulation is under the control of the sympathetic nervous system, and these nerves are well supplied to the various tissues of the eye, undoubtedly many, if not most of these are efferent, but undoubtedly also many are afferent, and control the circulation in the arteries of the eye Remembering how frequently the blood vessels are acted upon by purely nervous influences of varied character, and how quickly purely normal and transitory changes may be rendered pathological, I could not but imagine that some, if not many, cases of glaucoma were caused by the result, either of repeated sympathetic shocks to the muscles controlling the blood vessel system of the eye with resultant venous stasis, or even as the result of a single severe shock which acted as a paralyzant to the sympathetic system of nerves The idea is not new, as Donders long ago referred to this, but I believe that its therapeutic importance has not been enforced Von Graefe thoroughly recognized the importance of a variation of the vascular pressure as causative of glaucoma whether inflammatory or not He considered the origin of these variations to be intra ocular, but with our present knowledge of reflex action this restriction is unnecessary

That the pressure of fluid regulates the outflow so that when the afflux is increased a compensatory increase of the efflux occurs (Snellen) Can this hold good in an eye subjected to so frequent variations of pressure as occur in glaucoma? In regard to the effect of nervous shock as causative of glaucoma, I may quote Laqueur, who states that the symptoms of glaucoma often appear after sudden attacks of fright or anger, after sleeplessness, violent and exhausting labor, etc Several cases which have occurred lately in my own practice have brought the same facts frequently before me

Case 1—Mary F aged 41, four living children, two dead, no miscarriages Says 'Enjoyed good health until ten years ago since which time has been exceedingly nervous, following an attack of typhoid fever (Case referred by Dr John H Locke) Sight good until the sudden death of husband, at which time she fainted, on recovery from the faint found herself blind in the right eye with partial loss of vision in the left Ten days later acute inflammatory glaucoma in both eyes Marked hysteria and melan-shows that since the disease first appeared there the number of cases has been 136 Fourteen cases are now under treatment at homes and the hospital Thirty-nine convalescents are reported The same number are well, but have not been discharged Thirty-one cases have been cured There have been sixteen fatal cases Last week $1,000 was appropriated from the State epidemic fund to aid in suppressing the disease The Governor will decide to day how much will be allowed for the next seven days The cases are being concentrated at the hospital, and it is thought that not so much money will be needed —*Indianapolis News*, Oct 13, 1893

A Professional Beautifier —A certain Dr Robert Fisher, a professional beautifier of Vienna, has been revealing the secrets of the trade He declares that many mothers put their daughters through a whole course of beautification before marriage The doctor divides his treatment into the negative and the positive By means of the first method he removes blemishes that exist and by the latter he improves the good points that nature has already given the subject He has even gone so far as to invent a "tear pump," designed to aid in the timely display of emotion —*N Y Sunday Mercury*

Looking for a Hospital Site —Drs William H Ford, E O Shakespeare and William Welsh, who were appointed several months ago by the Mayor to select a site for a new municipal hospital, with that object in view, have visited several places in outlying districts The present hospital location, it is said, retards the progress of building operations in the northern section of the city, while the proceeds to be obtained by a sale of the property with its large grounds would be ample to secure far better accommodations for the treatment of contagious and infectious diseases —*Philadelphia Public Ledger*

N Y Pasteur Institute —The commodious new building of the New York Pasteur Institute, which is beautifully situated in Central Park, at the corner of 97th Street, was opened with appropriate ceremonies on October 9th Addresses were delivered by Dr Paul Gibier, the Director of the Institute, by Prof R Ogden Doremas, and by Vicomte d'Alzac, Consul General of France, after which a collation was served

The Mayor did not Approve —The authorities of the city of New Haven rejected the recommendation of the Board of Health for the establishment of a contagious disease hospital The mayor is reported by the *New Haven News* of October 11, as saying he preferred to have the general hospital take care of these cases! Sapient Mayor!

Infant's Hospital —An infants' hospital is to be established at Athol Springs, thirteen miles from Buffalo, by the "Fresh Air Mission" of that city Dr Eugene Smith of Detroit, has sold to the Mission the Athol Springs Hotel and the Spring House The hospital is intended to be used in the summer only

Punished for a Wrong Diagnosis—The Chinese Way —Four members of the Imperial College of Physicians at Pekin, who failed to give a proper diagnosis of the Emperor's recent indisposition, were punished by having a year's salary taken away from them

Legacy to Philadelphia Hospitals —The Ingersoll estate was partially divided, October 11, by which the Episcopal Hospital, the Children's Hospital and the Consumptives Home, all of Philadelphia, each received one third of $476,574,67, the residue on hand at the date of the distribution

Suffering at Brunswick —Great suffering prevails at Brunswick, Ga, on account of the yellow fever epidemic, and the inhabitants have appealed for relief Many supplies hav been sent, but there is still greater need of supplies tha ever It is not likely that the situation will improve unti after frost

Dr Harry B Faville of Madison, Wis, has accepted the chair of general medicine in the Chicago Policlinic He will still live in Madison as but one half his time will be needed in his college work

Won his Case —Dr J E Reeves of Chattanooga, who was sued for damages by the "Amick Consumption Cure" Company, for denouncing the concern as fraudulent, won his case in court

He Failed to Notify the Board of Health —Dr Leander A Cliffe of Roxbury district, Boston, was arrested and found guilty of violation of law for failure to report a case of diphtheria

Sanitarian Injured —Dr Lewis Balch, Secretary of the State Board of New York, received a painful injury by being thrown from a horse near Albany on the 7th instant

Emergency Hospital —An emergency hospital was dedicated with appropriate ceremonies, at Nashua, N H, October 1

A New Hospital was opened at Little Falls, N Y, on October 16 by the Hospital Association of that city,

Dr R Harvey Reed of Mansfield, O, has been appointed consulting surgeon to the "Big Four" railroad

The New Hospital Building at the Soldiers' Home, Milwaukee, has just been completed

A Hospital for contagious diseases has just been completed at Spokane, Washington

THE PUBLIC SERVICES

Army Changes Official list of changes in the stations and duties of officers serving in the Medical Department U S Army, from October 7 1893 to October 13 1893

First Lieut GEORGE D DE SHON, Asst Surgeon is relieved from further duty pertaining to the medical section of the War Department Exhibit World s Columbian Exposition, Chicago, Ill and will return to his proper station Ft D A Russell, Wyo

First Lieut ALLEN M SMITH Asst Surgeon will proceed without delay to Ft Missoula Mont and report to the commanding officer of the post for temporary duty to enable Capt WILLIAM D CROSBY Asst Surgeon to take advantage of the leave of absence granted him

Capt GEORGE McCREERY, Asst Surgeon U S A (Ft Sidney Neb) granted leave of absence for one month to take effect about Oct 15 1893

Navy Changes Changes in the Medical Corps of the U S Navy for the week ending October 14 1893

Medical Inspector GEORGE H COOKE from Navy Yard League Island, Pa and to special duty in Philadelphia Pa

Surgeon E Z DERR ordered to Navy Yard League Island, Pa

Surgeon B S MACKIE, detached from duty in Philadelphia Pa and wait orders

ORIGINAL ARTICLES

THE ORIGIN OF GLAUCOMA AND A SUGGESTION AS TO ITS EARLY MANAGEMENT

Read in the Section on Ophthalmology at the Forty fourth Annual Meeting of the American Medical Association

BY LOUIS F LOVE, M D
OPHTHALMIC SURGEON TO ST MARY'S HOSPITAL, ETC
PHILADELPHIA PA.

I do not desire to present any novel ideas with regard to the origin of glaucoma, or to recommend any special treatment of its earlier manifestations My object is rather to direct attention to what I believe to be the principal cause of glaucoma simplex and acute inflammatory glaucoma, and to suggest the use of well known remedies for a condition which may prove the starting point of the disease The nature of this obscure trouble has always been a subject for speculation, from the earliest days of medicine, but it is only comparatively recently that its pathological character was understood The work of the anatomist, the physiologist, the pathologist and the clinician have shed much light upon what was obscure to the older physicians Until the time of von Graefe the character of glaucoma was very obscure, his discovery of its general character was a very great step forward, but left unexplained how or why the increase in intra ocular pressure was caused The circulation in the eye, and the nature of the ciliary body were then not understood but von Graefe was shrewd enough to refer the cause of the pressure to a disturbance of the circulation When the anatomist and physiologist had made clear the wonderful method by which the nutrition of the structures of the globe is maintained and had proved the existence of a current from the ciliary body through Schlemm's canal and into the triangular space, it was seen how obstructions of these small channels might readily cause such a disturbance in secretion and excretion as might cause an increase of intra ocular pressure and thus the symptoms of glaucoma and, if maintained, the disease itself (Knies and Weber)

Any cause which produces a rise in the intra ocular pressure will give rise to some, at least, of the common symptoms of glaucoma They may be produced temporarily in the normal eye by a simple practice that I have often adopted If the head of a subject possessing normal eyes is held in a dependent position and at the same time pressure is made on the eyeball for a short time, the subjective symptoms produced will be similar to those of disease The globe becomes tense to the trained touch, chromatic rings surround a bright point of light and these symptoms accompanied by severe pain, if the experiment is carried far enough, and occasionally ciliary neuralgias are produced These symptoms are evidently due to a disturbed circulation, and the study of the pathological conditions existing in glaucoma has confirmed the reasoning of the anatomist and physiologist The cupped disc shows the effect of the intra-ocular pressure and where inflammatory processes have been set up their effects are found in the ciliary region The cause of the increased intra-ocular pressure has therefore been justly assumed to be a disturbance in the fluid circulation of the eye But what should cause a disturbance in a body so remote from external influence as the ciliary body? To this question no entirely satisfactory answer has yet been made, and I would therefore suggest that a further inquiry be made to determine the more remote causes of these changes in the circulation It is very well known that the blood circulation is under the control of the sympathetic nervous system, and these nerves are well supplied to the various tissues of the eye, undoubtedly many, if not most of these are efferent, but undoubtedly also many are afferent, and control the circulation in the arteries of the eye Remembering how frequently the blood vessels are acted upon by purely nervous influences of varied character, and how quickly purely normal and transitory changes may be rendered pathological, I could not but imagine that some, if not many, cases of glaucoma were caused by the result, either of repeated sympathetic shocks to the muscles controlling the blood vessel system of the eye with resultant venous stasis, or even as the result of a single severe shock which acted as a paralyzant to the sympathetic system of nerves The idea is not new, as Donders long ago referred to this, but I believe that its therapeutic importance has not been enforced Von Graefe thoroughly recognized the importance of a variation of the vascular pressure as causative of glaucoma whether inflammatory or not He considered the origin of these variations to be intra ocular, but with our present knowledge of reflex action this restriction is unnecessary

That the pressure of fluid regulates the outflow so that when the afflux is increased a compensatory increase of the efflux occurs (Snellen) Can this hold good in an eye subjected to so frequent variations of pressure as occur in glaucoma? In regard to the effect of nervous shock as causative of glaucoma, I may quote Laqueur, who states that the symptoms of glaucoma often appear after sudden attacks of fright or anger, after sleeplessness, violent and exhausting labor, etc Several cases which have occurred lately in my own practice have brought the same facts frequently, before me

Case 1 —Mary F aged 41, four living children, two dead, no miscarriages Says 'Enjoyed good health until ten years ago since which time has been exceedingly nervous, following an attack of typhoid fever (Case referred by Dr John H Locke) Sight good until the sudden death of husband, at which time she fainted, on recovery from the faint found herself blind in the right eye with partial loss of vision in the left Ten days later acute inflammatory glaucoma in both eyes Marked hysteria and melan cholia The case progressed in the usual manner Iridectomy on both eyes

Case 2—Mrs K, aged 55, eight children, three living, no miscarriages Says always enjoyed comparatively fair health Dates the gradual loss of vision from the time of an unfortunate accident, causing the loss of several lives for which her son was in a measure responsible Left eye absolute glaucoma, right eye glaucoma simplex Iridectomy on right eye

Case 3—K H, aged 39, married, no children, no miscarriages Dating from sudden death of father and subsequent family trouble her sight has been more or less bad, large, deep glaucomatous cup in right eye, shallow excavation with tapering of veins in the left eye Arterial pulsation, increased tension, patient refused operation

Case 4—F O, aged 55 years, cigar maker, patient profoundly neurasthenic and hysterical, similar history as to family troubles and great mental strain Case of glaucomous simplex

In all of the above cases they were referred to their accustomed medical attendant, no organic trouble was reported with the exception of the second case, where albumen and casts were found in the urine

I do not wish to be understood as insisting that every case of glaucoma simplex, or acute inflammatory glaucoma has necessarily a nervous origin, or that the disease is *always* caused by reflex action through the sympathetic nerves I believe, however, that a majority of cases can be traced to a nervous starting point, and it is to the cases thus caused that I wish to direct your attention

The prodromes of glaucoma are exceedingly obscure, occasionally they seem to be wanting altogether, but cases not rarely occur in which, while there is no definite indication of glaucoma nervous symptoms manifest themselves which indicate the possible development of the disease Such cases if looked for will develop in every ophthalmologist's practice and while it is of all the difficult problems of medicine, most difficult to prove "what might have been," observation has convinced me that glaucoma can be warded off, so to speak, by the use of the best means known to the neurologist for strengthening the nervous tone In this event the case passes from the care of the ophthalmologist to the expert in nervous diseases, but I have seen in my own practice most beneficial results from the use of strychnia in moderately heavy doses, and in one case especially a long sea voyage has resulted apparently at least, in the prevention of the threatened disease I do not think that the ophthalmologist should be called upon to treat such cases but they should be given the best advice as to hygiene and medicine that the present status of medical progress affords As to the effect of electricity either local or general in such cases, I am not in a position to speak, but I believe that it might be highly beneficial

Of course after the disease has developed there is nothing but the old routine to employ Early iridectomy and the use of eserine comprehend the sum total of the treatment It is in the earlier stages of the disease that the glaucoma offers the best prospect for useful therapeutic study, and it is to direct your attention to this study that I have engaged so much of your time

I do not think our present knowledge of nervous irritation or sympathetic secretion is sufficient to enable us to make a very good defense of the theory that glaucoma is a nervous affection, but practically I think if we take careful histories of our glaucomatous cases that we will find nervous symptoms predominate

1 Early symptoms, doubtful name of term
2 Poor accommodation effort
3 *Neurotic conditions*, neuralgia, etc

POSTERIOR SCLEROTOMY AS AN IMMEDIATE PRELIMINARY TO SOME OPERATIONS FOR GLAUCOMA

Read in the Section on Ophthalmology, at the Forty fourth Annual Meeting of the American Medical Association

BY H GIFFORD, M D
OMAHA NEB

The proposition which I wish to maintain is that when the intra ocular tension is high, a small incision through the sclera into the anterior part of the vitreous, made immediately before the various operations for glaucoma in which the anterior chamber is opened, greatly lessens the dangers which ordinarily attend such operations These dangers are in brief 1, that the iris may be wounded or the incision into the anterior chamber be improperly made on account of the shallowness of the chamber, 2, rupture of the suspensory ligament with loss of vitreous or sublaxation of the lens, 3, tardy healing of the wound, 4, failure of the anterior chamber to refill, 5, failure of the operation to immediately relieve the high tension, 6, rupture of retinal or choroidal vessels

That a small incision into the vitreous, made two or three minutes before a glaucoma iridectomy, for instance, must greatly lessen these dangers is, I think, obvious from a moment's consideration of the conditions With rare exceptions, glaucomatous eyes are hard because there is too much fluid in the vitreous, a scleral incision about one-eighth inch long, allows this excess of fluid to drain off without permitting the escape of any appreciable amount of the vitreous jelly The contents of the vitreous chamber being thus lessened, its tension becomes, for an instant, less than that of the anterior chamber, and the latter immediately tends to become deeper, thus facilitating any incision into it, beside tending to break up any adhesions which may have formed at its filtration angle With a low pressure in the vitreous, the danger of a rupture of the zonula must of course be less than when the pressure from behind is high It is equally plain that the preliminary sclerotomy favors a prompt closure of the wound and decreases the chance that at the evacuation of the aqueous the iris may be so firmly pressed against the cornea as to retard the refilling of the anterior chamber, or perhaps prevent it entirely, as in the cases of so called malignant glaucoma Whether the danger of rupture of the retinal or choroidal vessels be lessened by a preliminary sclerotomy may be questioned, since when it is done, the two incisions probably remove more fluid from the eye than a simple iridectomy would, it might be held that the danger of internal hemorrhage would be increased, but where the sclerotomy is made slowly and the vessels are allowed a few minutes to accommodate themselves to this first reduction of pressure, I think the chances are at least even, that the total danger to the vessels is not increased

I make the scleral puncture, sub conjunctivally, with a sharp von Graefe knife, at a point near the outer border of the inferior rectus one fourth inch from the limbus, enlarging the cut to a length of about one eighth inch Made in this way the additional risk involved is practically zero, and by injecting a drop or two of cocain solution under the conjunctiva, the scleral cut is rendered as painless as the corneal section

Primary glaucoma is a rare disease in my region, so much so that in the last two years I have had but four cases in which the preliminary sclerotomy seemed to be called for, and I feel like apologizing for the small amount of clinical material which I have to illustrate my theoretical conclusions In two of these cases it was made immediately before making an iridectomy, with an excellent result in each case In the other two cases, an iridectomy had already been made and the scleral incision was used as a preliminary to extracting what remained of the lens In one of these, the patient was Miss T , age 27, who came to me about Sept 15, 1892, with the history of glaucoma of the left eye of several years' standing Two years before, a broad iridectomy had been done elsewhere without permanently relieving the tension The eye was sightless and painful at times, with tension + 2 A broad posterior sclerotomy was made with only temporary relief, and as the patient was much averse to enucleation, I extracted the cataractous shrunken lens Before making the corneal incision, however, I made a posterior sclerotomy and had the satisfaction of extracting the lens with a sharp hook without the loss of a particle of vitreous from the corneal wound The operation afforded relief for but a short time, however, and in the course of six weeks the eye was eviscerated The case simply indicates the advantage of the preliminary scleral incision when the lens has to be extracted from a hard eye, for without it the extraction in this case would almost certainly have been followed by a gush of vitreous

The fourth case illustrates the same principle, but as the history exhibits the unusual feature of glaucoma developing after a broad preliminary iridectomy for uncomplicated cataract, together with one of the so called spontaneous cures of cataract, I give it in detail A F , age 56, German, came to me April 15, 1887, on account of blindness of the left eye I found the eye to contain a nearly mature cataract, rather whiter than the average, with nothing else abnormal to be seen about the eye Light sense and projection first rate The other eye showed slight central opacities of lens, but was otherwise normal, V = 20 50 + A preliminary iridectomy was made on the left eye and contrary to my present custom it was made fully as broad and peripheral as the average glaucoma iridectomy The healing was normal and the patient left the hospital in a few days During the next five years the man was seen once or twice but showed no perceptible change in either eye On Feb 18, 1892, he returned, stating that the sight of the left eye still remained unchanged (he could count fingers) up to the end of December, 1891, when the eye began to pain him and the sight to get worse To my surprise I found the eye blind except for uncertain light perception at the outer side of field, no projection $T + 1\frac{1}{2}$, eye injected and painful The cataract had undergone spontaneous resorption with the exception of the greenish-yellow nucleus, which was dislocated downward and bobbed about with the movements of the eye A red reflex could be obtained from the fundus but no details could be made out No history of a trauma could be elicited Right eye as at first examination V = 20 40 — with + 1 D Without having much faith in the theory, I proceeded on the supposition that the movements of the nucleus might keep up the glaucoma, and extracted it with a sharp hook after a preliminary posterior sclerotomy, without losing a particle of vitreous at the operation After forty-eight hours a minute bit of vitreous was found between the lips of the corneal wound, but this soon disappeared and the healing was otherwise normal Some weeks afterward the man had a slight attack of pain in the eye but with this exception the relief afforded by the operation has been permanent The occurrence of primary glaucoma after a broad iridectomy is rare, if not unique The coincidence of glaucoma with spontaneous resorption of the cataractous lens has recently been noted by Witvalsky, and in my case, as in his, the onset of the glaucoma probably preceded the beginning of the resorption of the lens

The case which led me to make posterior sclerotomy as a preliminary to glaucoma operations was that of a boy, aged about 11, who for years, and probably from birth, had had tremulous irides As the result of a blow on the left eye, the lens was dislocated into the anterior chamber, with the immediate development of glaucomatous symptoms, which had persisted for several days when I was called I found the eye very hard and painful (V about 0, but no record made of it,) with the transparent lens pressed against the cornea doubling up the iris at its periphery As I knew from an examination made two years before, that the eye had a fluid vitreous and a ruptured zonula, I hesitated about extracting the lens with so high a tension I therefore made a scleral puncture below, which at once relieved the tension and after some hours, the lens was found to be in its normal position with the eye perfectly quiet The boy remained in the hospital for three days with no return of the glaucoma He averred that the sight of the eye was as good as ever, (this had always been the better of his two poor eyes) but disappeared before any accurate tests were made

It was not until recently that I learned that Weber (Arch f Ophthalmologie, xxiii, 1, 86) had proposed posterior sclerotomy to relieve the partial dislocation of the lens which occurs in the cases where, after a glaucoma iridectomy, the anterior chamber fails to refill The proposition is a good one so far as it goes, only I feel confident that if the sclerotomy were done before the iridectomy, such cases of malignant glaucoma would rarely, if ever, be met with

In employing posterior sclerotomy as an immediate preliminary to glaucoma operations, I supposed, until recently, that I was doing something entirely new All the handbooks at my disposal, including the large treatises of Graefe-Saemisch and De Wecker-Landolt, are silent on the subject, but on obtaining the valuable monograph of Priestly Smith on glaucoma, I found (p 161) the following passage "A scleral puncture is easy to make, nearly or quite painless and apparently safe, and it fulfills a definite purpose, namely, that of withdrawing fluid from the vitreous chamber so as to lessen for a time the pressure behind the lens I have many times employed it, and I think with advantage, as an auxiliary to iridectomy in cases of special risk, making the puncture in most instances, immediately before the iridectomy, in order to relieve the very high vitreous pressure before allowing the aqueous to escape, in cholia The case progressed in the usual manner Iridectomy on both eyes

Case 2—Mrs K, aged 55, eight children, three living, no miscarriages Says always enjoyed comparatively fair health Dates the gradual loss of vision from the time of an unfortunate accident, causing the loss of several lives for which her son was in a measure responsible Left eye absolute glaucoma, right eye glaucoma simplex Iridectomy on right eye

Case 3—K H, aged 39, married, no children, no miscarriages Dating from sudden death of father and subsequent family trouble her sight has been more or less bad, large, deep glaucomatous cup in right eye, shallow excavation with tapering of veins in the left eye Arterial pulsation, increased tension, patient refused operation

Case 4—F O, aged 55 years, cigar maker, patient profoundly neurasthenic and hysterical, similar history as to family troubles and great mental strain Case of glaucomous simplex

In all of the above cases they were referred to their accustomed medical attendant, no organic trouble was reported with the exception of the second case, where albumen and casts were found in the urine

I do not wish to be understood as insisting that every case of glaucoma simplex, or acute inflammatory glaucoma has necessarily a nervous origin, or that the disease is *always* caused by reflex action through the sympathetic nerves I believe, however, that a majority of cases can be traced to a nervous starting point, and it is to the cases thus caused that I wish to direct your attention

I make the scleral puncture, sub conjunctivally, with a sharp von Graefe knife, at a point near the outer border of the inferior rectus one-fourth inch from the limbus, enlarging the cut to a length of about one eighth inch Made in this way the additional risk involved is practically zero, and by injecting a drop or two of cocain solution under the conjunctiva, the scleral cut is rendered as painless as the corneal section

Primary glaucoma is a rare disease in my region, so much so that in the last two years I have had but four cases in which the preliminary sclerotomy seemed to be called for, and I feel like apologizing for the small amount of clinical material which I have to illustrate my theoretical conclusions In two of these cases it was made immediately before making an iridectomy, with an excellent result in each case In the other two cases, an iridectomy had already been made and the scleral incision was used as a preliminary to extracting what remained of the lens In one of these, the patient was Miss T, age 27, who came to me about Sept 15, 1892, with the history of glaucoma of the left eye of several years' standing Two years before, a broad iridectomy had been done elsewhere without permanently relieving the tension The eye was sightless and painful at times, with tension + 2 A broad posterior sclerotomy was made with only temporary relief, and as the patient was much averse to enucleation, I extracted the cataractous shrunken lens Before making the corneal incision, however, I made a posterior sclerotomy and had the satisfaction of extracting the lens with a sharp hook without the loss of a particle of vitreous from the corneal wound The operation afforded relief for but a short time, however, and in the course of six weeks the eye was eviscerated The case simply indicates the advantage of the preliminary scleral incision when the lens has to be extracted from a hard eye, for without it the extraction in this case would almost certainly have been followed by a gush of vitreous

The fourth case illustrates the same principle, but as the history exhibits the unusual feature of glaucoma developing after a broad preliminary iridectomy for uncomplicated cataract, together with one of the so called spontaneous cures of cataract, I give it in detail A F, age 56, German, came to me April 15, 1887, on account of blindness of the left eye I found the eye to contain a nearly mature cataract, rather whiter than the average, with nothing else abnormal to be seen about the eye Light sense and projection first rate The other eye showed slight central opacities of lens, but was otherwise normal, V = 20 50 + A preliminary iridectomy was made on the left eye and contrary to my present custom it was made fully as broad and peripheral as the average glaucoma iridectomy The healing was normal and the patient left the hospital in a few days During the next five years the man was seen once or twice but showed no perceptible change in either eye On Feb 18, 1892, he returned, stating that the sight of the left eye still remained unchanged (he could count fingers) up to the end of December, 1891, when the eye began to pain him and the sight to get worse To my surprise I found the eye blind except for uncertain light perception at the outer side of field, no projection T + 1½, eye injected and painful The cataract had undergone spontaneous resorption with the exception of the greenish-yellow nucleus, which was dislocated downward and bobbed about with the movements of the eye A red reflex could be obtained from the fundus but no details could be made out No history of a trauma could be elicited Right eye as at first examination V = 20-40 — with + 1 D Without having much faith in the theory, I proceeded on the supposition that the movements of the nucleus might keep up the glaucoma, and extracted it with a sharp hook after a preliminary posterior sclerotomy, without losing a particle of vitreous at the operation After forty-eight hours a minute bit of vitreous was found between the lips of the corneal wound, but this soon disappeared and the healing was otherwise normal Some weeks afterward the man had a slight attack of pain in the eye but with this exception the relief afforded by the operation has been permanent The occurrence of primary glaucoma after a broad iridectomy is rare, if not unique The coincidence of glaucoma with spontaneous resorption of the cataractous lens has recently been noted by Witvalsky, and in my case, as in his, the onset of the glaucoma probably preceded the beginning of the resorption of the lens

The case which led me to make posterior sclerotomy as a preliminary to glaucoma operations was that of a boy, aged about 11, who for years, and probably from birth, had had tremulous irides As the result of a blow on the left eye, the lens was dislocated into the anterior chamber, with the immediate development of glaucomatous symptoms, which had persisted for several days when I was called I found the eye very hard and painful (V about 0, but no record made of it,) with the transparent lens pressed against the cornea doubling up the iris at its periphery As I knew from an examination made two years before, that the eye had a fluid vitreous and a ruptured zonula, I hesitated about extracting the lens with so high a tension I therefore made a scleral puncture below, which at once relieved the tension and after some hours, the lens was found to be in its normal position with the eye perfectly quiet The boy remained in the hospital for three days with no return of the glaucoma He averred that the sight of the eye was as good as ever, (this had always been the better of his two poor eyes) but disappeared before any accurate tests were made

It was not until recently that I learned that Weber (Arch f Ophthalmologie, xxiii, 1, 86) had proposed posterior sclerotomy to relieve the partial dislocation of the lens which occurs in the cases where, after a glaucoma iridectomy, the anterior chamber fails to refill The proposition is a good one so far as it goes, only I feel confident that if the sclerotomy were done before the iridectomy, such cases of malignant glaucoma would rarely, if ever, be met with

In employing posterior sclerotomy as an immediate preliminary to glaucoma operations, I supposed, until recently, that I was doing something entirely new All the handbooks at my disposal, including the large treatises of Graefe-Saemisch and De Wecker-Landolt, are silent on the subject, but on obtaining the valuable monograph of Priestly Smith on glaucoma, I found (p 161) the following passage "A scleral puncture is easy to make, nearly or quite painless and apparently safe, and it fulfills a definite purpose, namely, that of withdrawing fluid from the vitreous chamber so as to lessen for a time the pressure behind the lens I have many times employed it, and I think with advantage, as an auxiliary to iridectomy in cases of special risk, making the puncture, in most instances, immediately before the iridectomy, in order to relieve the very high vitreous pressure before allowing the aqueous to escape, in others immediately after the iridectomy, because there was very little escape of aqueous and the eye remained unduly hard. Further experiments may lead us to employ it methodically in conditions of this kind." I hope that my own slight contribution, if it does nothing more, will attract to this opinion of so good an authority, some of the attention which it deserves. I should add that when the preliminary sclerotomy is made, the corneal incision is best made with the narrow cataract knife.

COMMENTARIES ON DISEASES OF THE LACHRYMAL PASSAGES

Read in the Section on Ophthalmology at the Forty-fourth Annual Meeting of the American Medical Association.

BY H. GRADLE, M.D.
CHICAGO.

The objective sign of disease of the tear passages, viz. the overflow of tears, varies in degree in different patients. From the history and by the personal examination, it can be learned that while the eyes of some patients water continuously as long as they are awake, others notice the watering only when exposed to wind, smoke or dust, or on using their eyes under the condition of eye strain. In this class of patients the tears accumulate only while some stimulus excites the tear gland, but in the first mentioned class the activity of the tear gland is a continuous one. As far as we know, the secretion of the lachrymal gland is, however, not a continuous one under normal circumstances. Thus it has been noticed in congenital, absolute impermeability of the tear passage and after surgical obliteration of the tear sac, that the tears appear only when some external stimulus calls them forth. If hence an eye waters when no such external cause accounts for it, there must be some morbid irritation which maintains the continual activity of the glands. It can be proven therapeutically that in some instances the source of this reflex secretion is an intra-nasal anomaly, but in others the origin of the reflex appears to be the disease in the tear passage itself.

Observation has taught me that it is of some importance to distinguish between these two classes of lachrymal disease, viz. the cases with occasional and the cases with continuous lachrymation, although in some exceptional instances it may be difficult to decide to what class the patient belongs.

In those cases in which lachrymation is not continuous it is sometimes so slight that the patient does not speak of it. Hence if an operator is not on his guard he may overlook the presence of a purulent dacryocystitis in operations on the eyeball. In other instances, relief may be sought for some secondary condition caused by the lachrymal disease, without the existence of the latter being known to the patient. I have seen two instances of chronic purulent conjunctivitis in which the patients did not at all mention watering of the eye, but where pressure showed pus in the tear sac. In both patients the conjunctivitis, hitherto rebellious to treatment yielded readily on attending to the lachrymal disease. I have also seen some instances of blepharitis and asthenopic complaints in which the prime cause, viz. an obstruction of the tear duct could be proven objectively, but could not be inferred with certainty from the patient's statements, an observation previously spoken of by Becker (Af. O. xix 3, p. 353).

On the other hand lachrymation by itself is not necessarily indicative of obstruction in the passages. Whenever the tears are secreted too fast, they can not be carried off by the healthy canal as is shown by physiological crying. Weeping hence occurs with normal passages in acute inflammation of the eye and sometimes also in consequence of eye strain. Nasal irritation, too, causes in some instances a flow of tears too copious for the capacity of the normal tear duct.

Since diseases of the tear passages are most frequently caused by nasal anomalies we find at times lachrymal obstruction associated with irritative lesions in the nose which determine a continuous flow of tears. The cure of the nasal anomalies may in such instances change the continuous to a periodic lachrymation, even though the lachrymal obstruction persists. In other instances, however no intra-nasal source of reflex lachrymation can be found, and the cause of the steady activity of the lachrymal gland must be sought in the disease of the tear passage itself.

According to my experience the prognosis of disease of the lachrymal passages is largely determined by the occasional or the continuous character of the lachrymation. When the eye waters only on exposure to wind and dust or on severe exertion the disease is, as a rule easily removed, while in those patients whose eyes water continuously therapeutic results have either been difficult to obtain, or were entirely unsatisfactory in my experience. It has seemed to me that the choice of the therapeutic method may determine the rapidity of the cure, but that the completeness and permanency of the results depend on the nature of the disease rather than on the mode of treatment. It may of course be suggested that these statements are self-evident, that mild cases are more easily cured than pronounced disease. But this would only be a play of words. For in some of the instances in which the watering is not continuous I have found a most decided obstruction or firm closure of the passage, while again in some cases of very rebellious dacryocystitis with unremitting flow of tears, the patency of the sac is scarcely interfered with or easily maintained. Moreover in considering a case cured or not cured, I do not depend alone on the symptomatic indication of the epiphora, but judge by the patency to the probe in cases of stricture or the presence of pus in dacryocystitis.

In the discussion of therapeutic methods and results it seems to me important to insist more on the distinction between stricture of the passages on the one hand, and dacryocystitis on the other, than is commonly done in literature. The two disorders are of a different pathological character and require different plans of treatment. It is common, however, to read of the same treatment used without discrimination in both affections. But what I have said of the influence of the lachrymation on the prognosis applies equally to both forms.

In obstructive disease of the passages I have largely employed the electrolytic treatment described by Jesop and Stevenson. The lachrymal probe is made the cathode of a current of four to six milliamperes lasting one to three minutes, shocks being avoided by creeping into and out of the circuit. A convenient way of doing this is to vary the pressure of the sponge or leather-covered positive electrode upon the well wetted skin of the face Where possible without much resistance I have entered the intact punctum dilated by a conical probe with a Bowman No 1 or even a fine platinum wire Where the punctum was narrow I have, however, nicked it After the current has passed a sufficient time but never more than three minutes, the probe which may have been grasped tightly by the walls while entering is felt to fit loosely It is hence possible to introduce a probe more easily while the circuit is closed than while it is open, provided there is no absolute closure of the passage

As the ultimate result of electrolysis I can present the following data while it is not frequent that permanent benefit is obtained from a single sitting, three to five electrolytic dilatations will restore the patency in most instances of lachrymal obstruction in which lachrymation is not continuous, It is thus a quicker mode of relief than ordinary probing Its greater efficacy I have likewise observed in comparative trials on the two eyes of the same patient, and in some of the more tedious cases by using the same probe at alternate times with and without the current But when no probe can be made to enter without undue force, it is less painful to the patient and as far as I can tell more useful in the long run to make at once a thorough Stilling's incision If after this the patency does not persist I have sometimes found it advantageous to use probe No 6 with electrolysis But there are instances with much continuous weeping in which it is not possible to keep the passage open by any therapeutic means The prognosis, however, is better if the continuous lachrymation is of nasal origin If in such cases the causative nasal anomaly can be removed, the weeping changes into the intermittent type and the tendency to reestablishment of the stricture ceases

In purulent dacryocystitis the results obtained by a free internal incision depend on the condition of the sac membrane My experience leads me to think that this is indicated by the degree of lachrymation In any instance in which the eye was ordinarily dry except when irritated by the usual stimuli of lachrymal action, the purulent secretion diminished progressively from the time of the operation It is in this class of cases that Stilling's assertion so ably defended by Thomas last year, applies literally, viz that a single incision is sufficient for a cure without subsequent probing The result has been the same, both where the knife met with considerable resistance and where the operation showed no real stricture But I have learned to lay stress on the regular evacuation of the sac by pressure In fact in very young children dacryocystitis will often heal by this procedure alone, without any incision whatsoever When the lachrymation due to an inflamed tear sac is a continuous process the incision is not so likely to lead to a permanent cure In some instances in which the caliber could not be maintained by the incision alone, electrolytic dilatation with large probes has been of service But there are cases, presumably those with polypoid degeneration of the sac wall in which the passage stays clear, but the purulent secretion and overflow of tears do not cease entirely Some of these I have been able to benefit by nitrate of silver injection (2 to 4 per cent) and others by nasal treatment But still there remains a minority of patients in whom the continual weeping and purulent secretion can only be cured by obliteration or extirpation of the sac

THE TREATMENT OF NASAL DUCT OBSTRUCTION

Read in the Section on Ophthalmology, at the Forty fourth Annual Meeting of the American Medical Association

BY CASEY A WOOD, CM , M D

PROFESSOR OF OPHTHALMOLOGY IN THE POST GRADUATE MEDICAL SCHOOL, CHICAGO OCULIST AND AURIST TO COOK COUNTY HOSPITAL OCULIST TO THE EMERGENCY HOSPITAL AND ALEXIAN BROS HOSPITAL

I find that some writers treat the whole subject of nasal duct obstruction in a sort of light and airy fashion, as if they were dealing with tarsal cysts or the removal of a foreign body from the conjunctival sac Others run along in a most gloomy vein, entirely discouraging to the seeker after surgical consolation in the hour of doubt

These facts have impelled me to bring before you some conclusions I have arrived at, regarding the treatment of this condition, both to introduce the subject and in the hope of hearing your criticisms

First of all, how shall we distinguish between true organic stricture of the duct, and obstructions due to swelling of the mucous membrane? I have come to regard the answer to that question as a necessary preliminary to treatment and I have mostly applied this test when the sac is enlarged and pus can be squeezed out of one of the puncta, an organic obstruction (at least stricture of the soft parts) is present, and I have rarely seen a case where even the most extended and carefully pursued treatment by syringing, irrigation or other procedure, preserving the integrity of the punctum and canaliculus, do more than palliate the discomforts of the case On the other hand, if there be little or no cystic swelling and the secretion be entirely mucous and not overabundant, the obstruction is a swollen or otherwise diseased mucous membrane and is, in a fair majority of cases, amenable to the milder kinds of treatment

Assuming that one must ferret out the first cause of the trouble in those cases where one has to deal with obstruction not of the organic kind, I feel certain that nasal diseases are the most important, an argument by the way, in favor of the oculist knowing something about the diagnosis of nasal troubles Further than that, there appears some reason for thinking that the mucous membrane lining the nasal canal is liable to atrophic obstruction (from inspissated mucus and muco-pus) in atrophic rhinitis, quite as much as from the swelling that goes along with the hypertrophic form Not enough is said about these matters The entrance of the duct into the lower nasal meatus bears I think, much the same relation to duct and sac and eye, that the neighborhood of the Eustachian entrance in the posterior nares holds to the tube, tympanum and internal ear We should know as much about it in treating nasal duct obstruction—especially in those conditions not the result of organic disease—as we try to discover of the Eustachian entrance in middle ear disease

It is often possible, particularly in the atrophic forms of nasal disease and in some other cases where cocain can be used, to see, if not the opening itself, at least the vicinity of that opening For this purpose I would suggest, when simple anterior rhinoscopy fails, a very small post-nasal mirror

Dr Emile Berger in his very instructive monograph (*Les maladies des yeux dans leurs Rapport avec la pathologie générale* p 165) pictures a mirror of this kind 4 mm in diameter but I think the larger sizes can often be used with better results If the neighborhood of the opening require special treatment, it should receive it quite apart from that administered to the nose as a whole

Having first proven by means of a small Bowman's probe—without the use of cocain which is likely to lead one astray—the patency of the canaliculus as far as the sac, *the amount of obstruction* within the duct (I do not mean its mere permeability) may be judged by the ease or difficulty with which one can inject watery fluid into the nose In my experience this procedure furnishes us with a fair indication as to whether in a given case the treatment is—other things being equal—likely to be prolonged or not

Coming to local treatment of the duct proper, I can not understand how, whether in cases of true stricture or not, the passage of the smaller probes, say Bowman No 1 or 2, through the intact punctum and along the intact canaliculus, into the nasal duct can possibly do any good I have often seen it do harm If introduced under cocain in sufficient strength to anesthetize the sensitive mucous membrane, abrasion of some part of the passage is sooner or later pretty certain to be produced Because it is not an easy maneuver, that of passing a probe of this kind so that its small, sharp end will strike the superior opening of the duct without injuring the membrane that covers it But if one does manage it upon every occasion—*cui bono?* It is not large enough in the first place, to exert a healthy action upon any form of obstruction I know of and does not, when once in, give us any information not more easily and more safely obtained by other means

Most cases of nasal duct obstruction—aside from stricture—can be cured by the local application of appropriate remedies, and it seems to me rational that the *sort* of local remedy is of importance Most observers speak in a vague way about the nature of these, but why should we not treat the swollen or otherwise diseased mucous lining *here* according to the local condition, so far as we know it, or are capable of guessing at it? Anel's or Meyer's syringe, and those patterned after them, as usually sold, have too large a point It is usually necessary in using them to first introduce the punctum dilator Again, the barrel is usually too small, requiring repeated removal and introduction of the point when much fluid is needed To remedy these defects I would suggest that a fine hypodermic needle, whose end has been cut off and rounded by a careful workman, should be attached to a good large barrel It is then less distressing to the patient and makes on the whole a more useful instrument With it one may flush the whole tract painlessly, easily and effectually

Far better than any of these, when the duct is moderately patent, is the lachrymal irrigator which anybody can have made at a small cost It is nothing but a reservoir, best placed ten feet above the patient's head, a piece of rubber tubing, a stopcock and the altered hypodermic needle aforesaid All the operator has to do is to introduce it (and it is much easier of introduction than the point of a lachrymal syringe) and irrigate as much as he pleases

Whatever I have done in these cases I rarely find that my patients present themselves often enough for treatment One must have some kind of supplementary home procedure, and I know of none more simple and effective than that which Gould speaks of in a paper published last year in the *New York Medical Journal* After a somewhat similar fashion I have been instructing my patients to help cure themselves for several years past They soon learn to keep the sac emptied—by pressing upon it and forcing its contents into the nose—and afterwards allowing it to refill with the curative fluid applied at the inner canthus

When stricture of the soft parts is present there is nothing for it but the knife and the use of the larger probes But with a proviso—it seems to me to be a very weak and ineffectual kind of surgical procedure, that of doing the one without some guarantee that the other will be persevered in for several months afterwards, if need be

Not many ophthalmic surgeons appear to entertain anything like that high respect for the intermediate lachrymal apparatus which its important functions seem to demand So far as I know, the slitting of a canaliculus is never followed by a restoration of punctum and small canal, so that the peculiar suction force, exerted mainly by Horner's muscle, is once more possible The ineffectual slit canaliculi that roam this and other countries will surely rise up in judgment upon us At any rate they serve to discourage the neighbors of their possessors from being operated upon in cases where an operation is loudly called for

How to introduce the probe and keep open the passage after the stricturotome has done its work—that is the rub I teach my patient to introduce his or her own probe It can easily be done within ten days after the use of the knife and is a real solution of the question I feel sure that the majority of patients will not come week after week and month after month to have probes introduced For one reason or another their attendance ceases, there is a relapse and one's reputation suffers in consequence I have and have had all sorts of people, children, delicate nervous women, busy men and others keep up their probing in a way which I am certain I could never myself have done Moreover the patient in this way, shares directly the responsibility of the case It is his or her diseased duct and a failure to comply with the contract lays the blame at the proper door

Finally, there is a class of cases in which in spite of long continued patient, diligent and in my judgment, judicious treatment, there still remains a troublesome amount of epiphora I do not know how to classify such cases nor am I very sure that I know why the lachrymation persists It seems to me the lachrymal gland is made to act in some peculiar reflex manner, by the abnormal conditions existing in or along the lachrymal passages and, as we can not entirely remove the cause—can not restore these passages in some cases to the status *ante quo*, the incitement to lachrymation remains

Dr Gould—I am sorry I arrived too late to hear Dr Gradle's paper in full, but I wish to say a word in regard to the plan of treatment which I have found successful in these obstructions of the lachrymal duct The patient being in a recumbent position, I flood the eye with a simple astringent and antiseptic solution Then emptying the sac by pressure, I again allow the solution to pass into the sac and duct, again pressing it out, and so on for several minutes twice or three times a day I have been carrying on this plan of treatment during the last year and have found only two cases where it was not successful It has certainly been satisfactory so far as my own practice is concerned, and I have received word from two or three others who have found it equally successful I find it often impossible to tell at a glance just what sort of stricture we have, and this at least is a ready means of differential diagnosis I believe it will effect a cure in all cases where the stenosis is functional, due to congestion, etc , but not of course when there is organic stricture

Dr Bettman—It seems to me that the division referred to by Dr Gradle is a very wise one indeed There are a great number of cases of epiphora where there is no stricture, but a hyper-secretion of tears due simply to reflex action from membranes of the nose In these cases I have been content to wash out the lachrymal passages, and if I find water passes through easily into the nose I am sure the duct is opened To the remark made by Dr Wood in reference to the introduction of probes by Becker, I would say that Dr Becker would not have been satisfied to use the 1 and 2 only, but he used 4, 5, 6 and 7 He passed them in rapid succession one after another, after having dilated the lachrymal duct with a No 5 Bowman, tapering to a fine point

THE CURVILINEAR REFLECTION OF WEISS AS A PRODROMAL SIGN OF MYOPIC DISTENSION

Read in the Section on Ophthalmology at the Forty fourth Annual Meeting of the American Medical Association

BY B ALEXANDER RANDALL, M A, M D

PHILADELPHIA

In a paper in the *Medical News* of Feb 9, 1889, the writer called attention to a phenomenon first described by Weiss at the Baden Baden meeting of German scientists and physicians ten years before, and asserted to be a prodromal sign of myopia Another report on the subject was made by Weiss to the Heidelberg Society in 1885, and his elaborate paper was published in Volume XXXI of Graefe's Archives The matter has since received little attention, and Dimmer's note in his Retinal Reflexes (Die Ophthalmoskopischen Lichtreflexe der Netzhaut), and my paper in English, (also in Kl Monatsbl May, 1889) are about the only further references to it The careful study of Dimmer corrects the one minor point in which my view of the causation of the appearance seems in error, and gives full scientific corroboration of the facts, so the phenomenon may be regarded as real and noteworthy in a number of cases, and the questions of its frequency and prognostic significance come more distinctly and urgently forward

Except to ophthalmologists of extreme "evolution" proclivities, the questions of the causation and progression of myopia constitute most important subjects of study, and concern closely all who practice eye surgery, whether they have many or few actual myopes to deal with Myopia is a condition of refraction, and any statement that it is in itself a disease, meets at once a refutation and a recoil on the part of some to the view that it is a beneficent adaptation of the eye to its requirements The excessive outcry about the "school-myopia" has done harm to the cause of school reform and impugned the honesty, as well as the judgment and observation of the reformers The vast bulk of good, bad and indifferent studies and writings on the subject leave only a sense of bewildered disgust in the mind of any but the careful critic, for to the same investigator must sometimes be credited the worst as well as the best of the observations The requisite critical analysis has not always been given to the divergent data and statements bearing upon the subject, and any and every view can obtain apparent confirmation among the host of contributions to the matter

A general collection and analysis of the material available was made by the writer in the *American Journal of the Medical Sciences* of July, 1885, and extended in papers before the International Ophthalmological Congress of 1888, the American Ophthalmological Society in 1890 and the Ophthalmic Section of the American Medical Association in 1890, in the endeavor to sift the truth out of the numerous hampering or contradictory details which surround it As a result of these studies it has seemed to me unquestionable that hypermetropia is the natural primary condition of the eye of the child and suffers little change with growth towards adult life through any normal increase of the dimensions of the globe It does, on the other hand, constantly tend to diminish, as the result of pathological distension due to inflammatory softening of the tissues, as evidenced by changes in the eye-ground, most commonly about the optic nerve entrance These changes have been variously explained, and their inflammatory nature combated by Stilling and others, but the minute observation of careful ophthalmologists demonstrates the reality of their inflammatory character The study, therefore of these conditions of conus, distortion and excavation of the papilla, the 'drag" (Thomson, *American Journal of the Medical Sciences*, October, 1875) of the vessels and every other phenomenon which can give warning of the advancing process is abundantly worthy of attention Among these phenomena this curvilinear reflex of Weiss certainly demands consideration, and it is a subject for regret that it has not received wider and closer study

The appearance consists in a curved line of brilliant reflex, generally at the nasal side of the optic nerve and nearly concentric with its margin, shimmering and shifting like the other retinal reflexes, but marked by a certain constancy of form and position Its conspicuousness is increased by the employment of an overcorrecting convex, or an undercorrecting concave glass, which has led Weiss to assign it to a position in the vitreous and to ascribe it to a collection of fluid interposed between this humor and the underlying eye ground Like all the retinal reflexes, it is best seen in this way, yet it can be traced to the retinal level and recognized as proceeding from its limiting layer It is evidently due to the curve of the retinal surface, caused by the prominence of this margin of the nerve, and Dimmer has shown that it is an inverted image and *must*, therefore, proceed, not from the convexity of the prominence, but from the concavity where this passes downward into the general retinal level Thus formed, the "reflex-bogenstreif" of Weiss indicates a real prominence at the corresponding margin of the nerve and not a hypothetical detachment of the vitreous It is met most commonly in distending myopic eyes, although also seen in those which are hypermetropic, and my impression that Weiss is correct in regarding it as prognostic of increasing distension has been strongly, if not precisely, confirmed by extended observation While as yet unprepared, however, to fully substantiate this view of its significance, I desire to bring forward here some facts with regard to it and again to ask for it the careful study of ophthalmic colleagues

The question of the frequency of the observation of this phenomenon must receive a slightly different answer since my more frequent employment of a strongly concave mirror in studying and seeking it, for like the other retinal reflexes, it is made much more conspicuous by this means Examining in the autumn of 1891, 365 boys in a Philadelphia school, I noted it in but 40 eyes, and found it the next year in 124 eyes or 16 per cent It was doubtless overlooked or unrecorded in some cases on each occasion, as the conditions of a hasty examination in which it constituted but a side issue were not favorable to an exhaustive search for it, but it was found in 11 per cent of H and 26 per cent of M yet it seems certain that the eyes in that school will show no such percentage as the 38 per cent of Weiss' average finding in a Manheim gymnasium, with 69 per cent among the myopic

As to its significance, no positive statement can yet be made It has certainly been conspicuous in a group of cases of progressive distension of the eyeballs and consequent increase in refraction, and I have regarded it as so probably of unfavorable prognosis that I have employed redoubled precaution in all patients presenting it, in the effort to obviate or minimize such a change Hence I could report a number of instances where there has not yet been any change in the refraction On the other hand, one or two cases of progression have been met where it was absent—first and last It may be hardly necessary to say again what I have previously stated in this section, that in my experience the tendency of myopia to progress is not the rule, as sometimes stated, but is the great exception Hence my opportunities for observing these cases are not very large, and it seems better to try to enlist others in the study, for I think those who have sought this phenomenon have found it with rather increasing frequency and have reason to regard it as a warning that deserves consideration

The primary claim of Weiss, that the curvilinear reflex is frequently quite difficult to see and is hardly, if at all, discoverable even in some cases where it is to be expected, has been abundantly corroborated At the focus of the retinal level it is often inconspicuous in the most marked cases, and as the macular region generally shows a deeper level than the nasal border where it is formed, overlooking of its presence is most natural The narrow pupil interferes somewhat with its ready investigation, but the flood of light admitted through a wide pupil tends to make less conspicuous all reflexes The numerous shifting reflexes along the vessels, especially in young eyes, can confuse the picture, since the Weiss reflex, unless marked and typical, may seem but one of them Indeed, until a striking case is encountered, even the ophthalmoscopist who has looked for the curvilinear reflex may remain skeptical as to its occurrence Once well seen, it can hardly fail to interest the observer and raise questions as to how often he has failed to recognize it in the past

Whatever the precise causes, efficient and secondary, of myopic distension, (and under this head I include all increases in the axial refraction), visible changes about the optic nerve entrance are the rule, and the posterior pole of the globe generally shows a measurable depression Concomitant with this there is apt to be a prominence of the nasal margin of the nerve, giving rise to the curved surface from which the reflection proceeds The view of Hasner, which Weiss advocates, that distortion is caused by the pull of a too short nerve, has certainly some show of probability and should lead us to seek carefully for evidence of this prominence of the nerve margin in all cases The result of such a study will certainly be that many instances of it are noted, that changes in it will be observed in certain cases followed sufficiently long, and that an additional series of interesting and probably important studies will be contributed toward the advancement of our specialty

The number of instances of this phenomenon which I have thus far observed, and the short periods of their study, do not permit of my drawing any sweeping conclusions I can only say that I have seen more tendency to increase of refraction in these than in any other group of cases, and am forced to regard the presence of Weiss' reflex as calling for special precaution and guarded prognosis, with regular periodical examination of the vision and refraction

---

A CASE OF PERSISTENT SPASM OF THE ACCOMMODATION, RELIEVED TEMPORARILY BY TENOTOMY OF THE EXTERNAL RECTI

Read in the Section on Ophthalmology, at the Forty fourth Annual Meeting of the American Medical Association

BY ALBERT RUFUS BAKER, M D
CLEVELAND OHIO

Miss P, aged 39, at the age of 33 began to suffer from headache, pain in eyes when reading In a few months was obliged to give up reading and using the eyes altogether Was treated by various physicians for nervous prostration, neuralgia, etc Finally advised to seek a change of climate A residence of several years in the West proving of no benefit she returned East for treatment

In May, 1892 she came under my care Family history good and her own health had always been good until the present trouble She is fairly well nourished, appetite good, bowels regular, sleeps well and no menstrual trouble or other difficulty Says she would be well if she could get relief from constant headache and pain in eyes when using them Headaches mostly occipital but much pain referred to temples and vertex

Upon examination, I found vision right eye 20-20 not improved with + lenses or cylinders, left eye 20-70 improved to 20-50 with + 1 D C axis 75, and an insufficiency of the internal recti of about four degrees for distance I ordered a pair of prisms 2 degrees each eye combined with cylinder for left eye, confidently expecting marked relief from headache Was much disappointed in finding that they were of no service I then resorted to the use of atropia and found a rather high degree of latent hypermetropia, and a slight astigmatism in right eye, vision under atropia uncorrected Right eye 20-70 with + 1 25 D S ⌣ 25 C axis 90, increased to 20-20 Left eye 20-100 with + 1 75 ⌣ + 1 25 axis 75 increased to 20-50 I prescribed right eye + 1 ⌣ 25 axis 90 ⌣ prisms base 2 in, and left eye + 1 25 S ⌣ + 1 25 C axis 75 ⌣ prism 2 base in and congratulated myself that I had made a very important discovery under the atropia and that all the difficulties would be at an end, but I was doomed to disappointment, and my patient with the expensively ground lenses was only able to see 20-100 with right eye, and 20-200 with left and notwithstanding a long, painful trial on the part of my patient the vision would not improve

I will not weary you in detailing all the changes

I made in these lenses, discarding the prisms, reducing the strength of the spherical lenses, bandaging one eye, systematically exercising the muscles with prisms, the persistent use of atropia at one time for three months without at any time relaxing the persistent spasm of the ciliary muscle. Dubosin, homatropin and the whole list of constitutional remedies including iron, arsenic, strychnia, zinc, phosphorus, anodynes, anti-spasmodics, coal tar preparations, etc., were used without benefit. It is not often that an intelligent patient will endure all the local and constitutional treatment I heaped upon her and being no better at the end of a year's treatment be willing to continue.

Although I have been performing tenotomy graduated and otherwise during the past nine or ten years, I still remain skeptical as to its relieving a case like the one under consideration, but after consulting with my friend Dr. Millikin, I determined to give it a trial. So I made a tenotomy of the left external rectus on April 1, and was greatly delighted on the following day to note that the patient could read 20 20 with right eye with + 75⌒25 axis 90 and 20-50 with +1 D⌒+1 axis 75 with left eye, the *first time there was any relaxing of the ciliary spasm* since the case came under my care excepting when under the influence of mydriatics. This continued for four or five days, patient was almost free from headaches. She was happy and so was I, and it was during this period of mutual congratulations that I sent the title of this paper to our secretary.

But our happy frame of mind was of short duration, the headaches gradually returned, the vision for distant objects became blurred with the spectacles. For a time she could see clearly in the mornings through the lenses, but later in the day everything became hazy and the old fashioned headache returned and at the end of two or three weeks was nearly as bad as ever. In the meantime a slight insufficiency of the internal recti of about two degrees again developed. A tenotomy of the right external rectus was made with no apparent benefit either to headache or vision. At present, the muscles are perfectly balanced for distance, a slight tendency to deviate outward for near vision. The headaches are as severe as ever. Mydriatics give slight relief from headaches as before the operation. It is altogether probable that in a few years with increasing presbyopia the patient will be relieved of her distressing symptoms of asthenopia, but I should not be surprised if she should suffer from some other reflex neuroses fully as painful.

I believe that nearly all the troubles we have with the muscles of the eyeball are due to, and are the direct outgrowth of the errors of refraction. This is generally recognized in cases of hypermetropia as a cause of strabismus. In most cases of muscular asthenopia we have the same excessive nervous stimuli sent to one pair of muscles that we do in strabismus, and those patients who have not sacrificed binocular vision, consequently suffer from pain and other nervous disturbances, due to the conflicting efforts at accommodation on the one hand, and those of convergence on the other. It has been my experience not infrequently in cases of errors of refractions, after correcting the ametropia to find that while I had relieved the pain due to the efforts at accommodation, I had disturbed the equilibrium that had become established between the efforts of accommodation and those necessary for perfect binocular vision, and thus set up a train of symptoms almost, if not quite as annoying as those from which the patient suffered before. And on the other hand, after performing a tenotomy of one or more of the recti muscles, I have relieved these patients of one kind of distressing symptoms, *only to be followed* by others fully as bad, so that I am skeptical as to the possibility of benefiting any case of asthenopia by a tenotomy in which prisms or the closing of one eye does not give temporary relief.

A pertinent question might be raised as to the frequency of persistent spasm of the accommodation. We oculists so frequently use atropia, prescribe spectacles, and if the patient returns complaining of a blurring of sight for distance tell him to continue the use of his glasses and the sight will clear up in time. Are we sure it does always clear up? Do not many of our patients discard our spectacles and return to their family physician or to the use of some popular headache cure to get relief? Or in these later days seek the advice of some of the *specialists—oculists* who make graduated tenotomies on every case in which there is a slight deviation of the eyes revealed by one of the many equilibrium tests. I think it was our genial ex-president Dr. Connor, who reported a patient upon whom thirty-two graduated tenotomies had been performed, without any marked relief of the asthenopia. I have seen several cases in which nearly as many have been done. I have a deviation outward revealed by this test of about four degrees in my own eyes, yet it causes me no inconvenience, and I should not allow any one to divide my external recti even partially.

These cases are all susceptible to mental impressions. They prove a fruitful field for quacks and charlatans in and out of the profession. They present the most brilliant cures effected by the *faith healers and Christian scientists*. The mental impressions of having had an operation performed will *effect* a temporary cure at least. Especially if the surgeon has enough of that peculiar attribute that inspires implicit confidence in the mind of his patient that the operation *will* cure.

A good illustration of this mania for operations is that presented by the "orificial" surgeons. Several of our Cleveland hospitals are filled with these patients so that it is difficult to find room for a patient needing a legitimate operation. It is the fashion now among certain classes of the community to have their rectum, *their* vagina, *their* urethra, and I am even informed in some cases, their umbilicus *stretched* by these "*orificial*" surgeons.

It has been my practice in these cases of asthenopia to first correct the error of refraction. If the asthenopia is not cured then resort to the use of prisms and the systematic exercise of the muscles. If the prisms, muscular exercise or the suppression of the image in one eye gives even partial relief I then propose a tenotomy, with considerable assurance that it will be of permanent benefit. But, in all cases in which no perceptible improvement can be obtained by the use of prisms, muscular exercise or closing one eye, I give a very guarded prognosis as to the result of a tenotomy, because in my experience the operative treatment of these cases has usually proved unsatisfactory. The *disease*, as I believe, frequently being the expression of a general neurosis and not amenable to ocular treatment.

SOME PRACTICAL EXPERIENCES WITH MUSCULAR ANOMALIES

Read in the Section on Ophthalmology at the Forty fourth Annual Meeting of the American Medical Association

BY T E MURRELL, M.D
LITTLE ROCK, ARK

I consider the Maddox rod the most valuable and reliable test for heterophoria that we possess Until I became acquainted with it I often had much trouble in arriving at any satisfactory conclusion as to the muscular tendencies Since its introduction diagnosis is in most instances made easy

The Graefe test is perplexing and unreliable in determining small errors in the lateral, and especially, in the vertical plane, the latter being extremely important even to so small an amount as half of a degree, which amount, and even less the rod test will quickly recognize The phorometer of Prince is a most convenient and ready application of the rod test, and is extremely satisfactory in detecting any error less than four degrees While far more accurate than any methods heretofore possessed for measuring the muscular balance, the rod test is not absolutely reliable owing to certain physiological laws resident in the visual act as will be shown further on

Since the very valuable contributions on the subject of heterophoria by Dr Stevens, with his comprehensive nomenclature for designating them, a new era has been opened up in ophthalmic practice Now that light has been thrown on this very important subject we can look back and recognize many cases in our experience that, for better knowledge we called retinal asthenopia, or some equally ambiguous title, and which after much vexation we relegated to the limbo of the incorrigible

No eye that is subject to tiresome vision is completely examined until the muscles are carefully tested for any tendency to deviate from a perfect balance This is now a rule with all accurate observers and we are astonished at the percentage of asthenopics who show some muscular anomaly In how far heterophoria depends on refractive errors, just as we know heterotropia does, is not yet clearly made out, but it is more than probable that some refractive fault, with or without an existing amblyopia, is at the bottom of nearly every such condition

I can hardly call to mind a heterophoric subject who was emmetropic, or had perfect vision in both eyes In view of this fact, some very competent men only correct the error of refraction and claim thereby to restore any want of muscular balance The most of us can not accept any such rule, although relief now and then comes under our personal observation, as in the following illustrative case

Mrs B , age 28, consulted me on account of inability to read or sew more than a few minutes consecutively without bringing on a severe headache and great distress Her general health had been greatly impaired by a confinement with severe lacerations some five month previous V=20-15 partly with either eye Ophthalmoscopic examination was made especially to settle a point of dispute as to the existence of a central lesion A normal fundus was found Under paralysis of the accommodation O D V=20-40 + 75 Dsph ⊃ + 25 Dcyl 90°=20 20 O S V=20 30 + 75 Dsph ⊃ + 25 Dcyl 90°=20 20 Rod test reveals an esophoria at twenty feet=10 degrees Ordered for her the cylinders for reading or sewing She wrote me a week later that the glasses gave her comfort A month later I heard that she could use her eyes more than she had done for months Not having the opportunity to see her and test her, I could not say positively the esophoria had disappeared, but certainly the asthenopia had, and this would lead one to infer also the esophoria According to a rule given further on, this case, with an esophoria of 10 degrees called for an operation

If one will carefully test all his refraction cases with the phorometer, he will find a large percentage of them show lateral deviations of a few degrees which, within a certain limit, say two or three degrees, I regard as physiological Repeated tests will show these deviations, however, to be variable The association between convergence and accommodation is so intimate that in many cases of either astigmatism or hyperopia uncorrected, we find an esophoria of two or four, or even more, degrees that calls for no special attention further than correcting the refraction By putting the accommodation in abeyance we may convert an esophoria, apparent or an orthophoria real, into an exophoria, as the following history will show

Mrs S , age 27, general health bad for a year, is very nervous at times and is subject to severe headaches Her physician sent her to me to see if her headaches and nervous phenomena could be induced by some ocular anomaly O D V=20 40 O S V=20 30 Ht=1 25 D each eye Orthophoria Ordered for her + 75 D sph for each eye for constant wear They seemed to relieve her for awhile, but she returned after two months complaining that the glasses did not relieve her any longer, although she could see better with them Rod test now shows exophoria=2 degrees at twenty feet and 8 degrees at twelve inches With prisms 1 degree each bases in, combined with the spherical glasses, she has easy vision

In the two cases just cited, we note the ill health and the nervous symptoms Heterophorias in my experience are most frequently found in the neurotic and, like refractive and other troubles in this class of people, are more difficult to relieve I have had under my observation at different times several members of one family, all of them of high nervous organizations, for refractive and muscular errors, in whom the most exact correction failed to give satisfactory results Hence they have gone the rounds of specialists, consulting the most eminent, with like unsatisfactory results in every instance

An eso or exo-phoria of a few degrees does not call for correction, unless there is well-defined asthenopia after the correction of any refractive error that may exist In these cases the addition of a prism or, when the result can be so attained, decentering the lenses will often give complete relief Those anomalous cases of esophoria for distance and exophoria for near, or sometimes the reverse, often do not admit of easy solution

Dr Stevens claims that in those cases of unstable balance of the lateral muscles, being at one time an esophoria and at another an exophoria, there is invariably a hyperphoria present This is a very wise and practical observation, and we should be careful in such conditions to carefully note the vertical balance There are exceptions to this rule, as will be seen from the following case that came under my observation

S K , age 8 years, complains of his eyes at school Says while reading the letters sometimes become mingled so that he can not distinguish one from another, but by looking off for a moment he again sees distinctly O D V=20-70 O S V=20 50 Paralysis by hematropin and cocain O D V=20-00, + 75 Dsph ⊃ + 25 Dcyl 90°=20 30 O S V=20 00 + 75 Dsph ⊃ + 25 Dcyl 90°=20 30

While watching him, I noticed one eye diverge fifteen or twenty degrees and instantly return to parallelism on my calling his attention On covering one eye while fixed on an object at 12 minutes it would diverge decidedly His mother now informed me that his eyes had always been doing this and were much worse when he was younger She said she had often noticed when he sat musing, that both eyes would seem to turn far apart, and that it used to be far more excessive and frequent than now He had binocular vision for all distances His convergence was about twelve meter angles, which he could hold for some time, in fact, he had a habit of looking excessively cross eyed for amusement On making the rod test I found no hyperphoria, but there was a variable lateral tendency There would sometimes be orthophoria and then exo- or eso phoria, the latter sometimes registering as high as eighteen or twenty degrees These wonderful acrobatic performances with his eyes astonished me The very strong tendency to deviate outward, as his mother had so often observed, and as was easily demonstrated by placing a screen over one eye would look like warranting an operation on the external rectus, but his very great power of convergence was a danger signal to any operative procedures So, desiring to watch the case longer, I determined for the present only to correct the small error of refraction He chose the minus rather than the plus cylinders, and expressed much satisfaction at the comfort they gave him A month later his parents went abroad and have not yet returned, but just before leaving I saw him and he said his glasses pleased him very much, and he had no complaints to make about his eyes In this case you will observe there was no hyperphoria, but it will be seen that after the most perfect correction of the refraction possible, vision was still barely two-thirds of normal, in other words, there is amblyopia, a chief factor, as has been already pointed out, in these heterophoric cases

We know that the vertical deviations are the most distressing, and can readily understand how they may so destroy the equilibrium of the eyes as to give rise to variable eso- or exo-phoria, but they are not the only factors in these conditions In fact the hyperphoria seems sometimes to be an after product of the eso or exo-phoria, and correcting the latter by an operation will very largely remedy the former The following case is interesting because of two features one, the persistence of troublesome diplopia in a case of long standing concomitant squint, and the other the presence of a hyperphoria which gave no trouble after the correction of the squint

Miss L, age 17 years, at 11 years of age began to have periodic squint, which became permanent at 14 years old She has been troubled with diplopia ever since the squint came on, varying with the squint when periodic and continuous since the squint has became permanent When I first saw Miss L I found the following conditions strabismus convergens of about 35 degrees with homonymous diplopia The squint is alternating but fixation is preferably with the left eye When the right eye fixes she has diplopia, seeing the false image with the left eye some thirty-five degrees to the left side She has no diplopia when the left eye fixes V=O D 20 40 O S V=20 20

Jan 16 Made a free tenotomy on right internal rectus, giving binocular vision immediately after the operation, and there was no longer diplopia in any direction

Jan 20 Under atropin O D + 4 Dsph V=20 25, O S + 2 50 Dsph V=20 20 Rod test now shows esophoria =16 degrees and right hyperphoria = 6 degrees, although she expresses much relief since the operation A prism of 6 degrees base down to right eye, correcting the hyperphoria, half corrects the esophoria The following glasses were ordered for her O D + 3 Dsph ⊃ prism 3° base down, O S + 2 Dsph ⊃ prism 3° base up With these she had easy and comfortable vision for some months April 25 She returns for further treatment as she is beginning to have diplopia again at times There is now a convergent strabismus of about fifteen degrees The hyperphoria is unchanged April 28 Made a careful tenotomy of the left internal rectus over correcting about four degrees Put in a suture correcting the excess May 2 Exophoria=8 degrees although she has ten meter angles of convergence Right hyperphoria = 5 degrees May 13 At twelve inches there is esophoria of three or four degrees and at twenty feet exophoria of same amount With the following glasses she has binocular vision at all distances O D + 3 Dsph ⊃ prism 3° base down O S + 2 Dsph

She returned home, wearing these glasses constantly, and a few months later she wrote me she was going to school and had no trouble with her eyes In this case, after correcting the esotropia the hyperphoria was corrected by a prism and the relief was complete, notwithstanding an exophoria for a distance and an esophoria for near

In adapting prisms for the correction of hetrophoria there can be no fixed rule, and in any given case it is very largely a matter of experiment The rule given with Prince's phorometer is, to correct one-half of a hyperphoria and from one-fourth to one half of an eso- or exo phoria I have found that we should correct almost, if not quite, the total hyperphoria where prisms are accepted at all, and a majority of the exophoria, while the proportion of an esophoria that will bear correction is usually one-half or less To avoid the constant use of prisms, which are so often unsatisfactory, the weak muscle is sometimes developed by a system of gymnastic training brought about by so placing prisms before the eyes as to increase the error already existing, and for the time forcing the muscle to do more work than ordinary While some surgeons claim satisfactory results from this system of treatment of insufficiencies, I must say I have found it tedious, laborious to the patient and in the end unsatisfactory in the majority of instances Perhaps the fault may be in the method and not in the principle, which is certainly philosophical to say the least

As commonly advised, prisms so adjusted as to put extra work on the weak muscles are to be worn a few minutes at a time, and the length of time increased daily If we but think a moment of the manner in which we go about developing the other muscles of the body we will see how very unnatural this is If, for instance, we want to develop the biceps we do not lift a weight, draw it near the shoulder and hold it there several minutes, and then lay it down until the next day, when we repeat the exercise in the same way, only holding it a little longer each day No, we alternately flex and extend the arm holding the weight, so as to contract and relax the muscles at short intervals This is the law that governs in all physical exercises where the development of a voluntary muscle is the end sought Why should not this same principle apply to the voluntary muscles of the eyes? I am indebted to my friend, Dr G C Savage of Nashville, Tenn, for the above suggestions He applies the principle to training the weak eye muscles in the following manner having adapted the prism of the required strength to give appropriate exercise to the weak muscle, the eyes are fixed binocularly on an object, say the printed letters of a page, for a few seconds (Dr Savage suggests ten), then the eyes are closed for a like period, when they are opened and again fixed on the printed page for a like period, thus alternately fixing and relaxing the eyes for several minutes at each time of exercise We in this manner imitate the ordinary methods used in developing the voluntary muscles in other parts of the body I have not had opportunity of testing this method, but it appeals to reason

There are cases, however, that will not yield to prisms or to orthoptic training and we then have to resort to surgery It is not always easy to draw the line between operable and non-operable cases but a very practical rule, already adopted by most of us, doubtless, has been published by the editor in the *Ophthalmic Record* which is whenever the red glass over one eye shows diplopia, or there is a hyperphoria of 3 degrees or an esophoria of 10 degrees we should operate To essay an operation on a muscle to correct an insufficiency of only a few degrees, requires of the surgeon much confidence in his ability to cope with the subject in hand The methods of operating differ somewhat with different surgeons, as do also their opinions and experiences as to the results from any given method or amount Some prefer very limited and repeated division of the tendon Others prefer to gauge the operation by the result desired beforehand, and to divide just so much tendon and no more and await the result, while still others, and this is my preference, carefully divide the tendon, stopping and testing frequently until the necessary amount of correction is obtained This seems to me the only practical method, and I seriously question the claims of those who say they can produce the result of a certain amount of division of the tendon Sometimes a total tenotomy will give no more result than a very limited division of the tendon will in other cases We are all aware of this in the operation for strabismus where such varied results are obtained from a clean tenotomy Another troublesome feature in these tenotomies is, that they do not always remain just where we leave them, what shows by the phorometer perfect correction on the completion of the operation will, in the course of some days or weeks, show either an over correction or an under correction

When the tenotomy, partial or total, gives an insufficient result the opposing muscle may be advanced, but in the heterophorias we generally have little trouble in getting enough result by tenotomy with almost no risk of proptosis Some cases of heterophoria are particularly obstinate to correction Whether there be such a thing as antipathy to single vision as taught by von Graefe, or whether the hyperphoria, as Dr Stevens declares, is always the cause of the difficult fusion, is a matter yet open to discussion The following case, which came under my observation, fully tested all my ability, patience and perseverance as well as that of the unfortunate sufferer himself

Mr J M, age 33, first consulted me June 27, 1892, for diplopia and great confusion of mind, inability to think connectedly and strange, heavy sensations about his head which he ascribes entirely to the condition of his eyes He stated that in January preceding he went to St Louis to consult a prominent specialist and recognizing an esophoria he prescribed prisms for him They gave him no relief The surgeon then made an operation on the left internal rectus muscle For awhile the operation gave relief, but after some days he had exophoria The left external rectus was now submitted to an operation, and not correcting the exophoria the right was operated These are the statements of Mr M on which I have to rely for the history of the case up to this time, as the surgeon in question failed to answer my request for a copy of his record of the case

The discomfort and confusion continued until I saw him five months later At that time I found the following condition on looking twenty-five or thirty degrees to the left he had crossed diplopia With a red glass over the right eye, looking at a candle twenty feet directly in front, he saw the red flame 6 degrees to the left and 2 degrees below the white flame The rod test showed exophoria = 6 degrees and right hyperphoria = 2 degrees taken at twenty feet There was no slanting of the lines to indicate involvement of the obliques Correcting the hyperphoria with a prism did not modify the exophoria On covering one eye while both were fixed on an object, near or far the covered eye would diverge decidedly O D V = 20-70, O S V = 20-20 Correction under suspension of accommodation O D + 50 D sph ⊂ + 50 D cyl 135° V = 20 03, O S + 1 D sph V = 20 30

I made a careful tenotomy of the right external rectus, testing several times until the images were brought together

June 28 Exophoria = 3 degrees and right hyperphoria = 1 degree or less June 29 No change Divided the tendon of the left external rectus, stopping and testing frequently, and got no result until the last fibers were divided when there occurred an over correction of 4 degrees A suture was put in, drawing the muscle back sufficiently to leave an under correction of 1 degree June 30 There is now less than one half degree exophoria for twenty feet, practically parallelism July 2 Lateral balance good for twenty feet, the vertical band of light running directly through the candle flame There is a right hyperphoria = 1 degree He expressed himself as greatly relieved, his head feeling clear, the mental confusion gone, and no diplopia He went home instructed to wear glasses and return in two weeks for further examination He wrote me occasionally and expressed himself in such glowing terms of the relief he had obtained that I, as well as he, thought it unnecessary for him to again visit me In about two months his old troubles began to return and he was again annoyed with diplopia and mental confusion

October 29 Examination of Mr M showed the following condition at twenty feet esophoria = 4 degrees, right hyperphoria = 3 degree, at twelve inches exophoria = 8 degrees I now added a prism to his glasses to correct the hyperphoria, but it gave no perceptible relief November 28 Right hyperphoria = 3 degrees, esophoria at twenty feet = 1 degree Exophoria at twelve inches = 14 degrees As he complained now chiefly of inability to converge comfortably to the reading point, I decided to reduce the exophoria at the risk of causing diplopia for distance Having apprised him of this, and obtained his consent to the operation, I divided the tendon of the left external rectus, giving orthophoria at twelve inches and esophoria at twenty feet = 24 degrees He now had more or less constant diplopia, when looking off from him, but had easy fusion at twelve inches There was now manifested a right hyperphoria of 5 degrees, and so I made a partial tenotomy of the right superior rectus bringing the images to the same level The following morning the hyperphoria had returned and measured 3 degrees I divided very carefully a small lateral strand of the tendon, getting complete correction I sutured back the left external rectus, dividing the eso- and exo phoria for a distance and near about equally, giving 12 degrees of each With a prism of 12 degrees base out before one eye he had ready fusion at twenty feet December 28 Still fuses readily at twenty feet with 12 degrees prism, but the rod test shows a right hyperphoria = ½ degree There was annoying homonymous diplopia for distance, and so I made a partial tenotomy of the left external rectus, bringing about easy and perfect fusion at twenty feet December 30 The lateral balance is still preserved but there is a left hyperphoria of 2 degrees Put a suture in the right superior rectus and drew it forward slightly December 31 There is now the most perfect balance he has ever had there being orthophoria for all distances January 13 Writes that his diplopia and confusion are returning February 16 Esophoria = 14 degrees at twenty feet and left hyperphoria = 4½ degrees Made a careful partial tenotomy of the left superior rectus, frequently testing until sufficient correction was obtained The esophoria now measured only 7 degrees or a reduction of one-half February 17 There is no diplopia and the rod test shows a left hyperphoria of less than ½ degree March 18 Esophoria = 16 degrees at twenty feet, and right hyperphoria = 3 degrees the eyes having traveled through a circle and come back to about where they were in the beginning Prisms gave him no relief He was now very little annoyed by diplopia and expressed himself as feeling much better than formerly Nothing daunted I again operated, this time dividing the tendon of the right internal rectus, getting no result whatever until the entire tendon was divided and the hook swept widely This overcame the esophoria and brought the eyes to a very nice balance, the hyperphoria almost entirely disappearing after the tenotomy

May 14 Mr M has gotten along very well since the last operation, two months ago, but there is still some confusion of vision, especially for reading He has diplopia when looking to the extreme right or left due to loss of motility but this gives him no trouble as it does not come in the way of ordinary vision Examination with the phorometer now reveals a right hyperphoria = 1½ degrees, and an exophoria at twelve inches = 12 degrees, but at twenty feet there is orthophoria in the horizontal plane Correcting the hyperphoria with a prism does not influence the exophoria With the following O D prism 1½ degrees base down, prism 2 base in, O S prism 2 degrees base in he has easy and comfortable vision for reading distance As he is only now troubled with the want of converging power in addition to the vertical deviation these glasses correcting these two faults give quite comfortable vision for reading After all the numerous tenotomies on Mr M there is no proptosis and the motility of his eyes is not perceptibly diminished

What the final result is going to be one can not say, judging from the record of the case as here given with all its mutations This case also very aptly illustrates those strange nervous phenomena pointed out by Stevens and others, due to want of balance in the ocular muscles In his worst condition he could not trust his memory, and was afraid to change money in business transactions lest he should make a mistake He seriously considered having one eye destroyed as he had been led to believe, and had so reasoned with himself, that this would put an end to all his annoyance

The case was pronounced hysterical by the gentleman whom he visited in St Louis, but I am disposed to credit his ailment to the muscular anomalies, solely for the reason that whenever he made most complaint of mental confusion I always found the most troublesome heterophoria I have selected the foregoing cases to illustrate certain anomalies to the rules, as we understand them, at this stage of advancement in this comparatively new field of surgery and which, I trust, will in some small way help on to the perfecting of our methods of dealing with these very important as well as very annoying conditions

Dr Savage—I always like to give a reason for the faith that is within me, but not being able to do so in so short a time as five minutes, I must refer you to the last issue of my journal, to the two papers, one on "Rhythmic Exercise, the Proper Method for Developing the Ocular Muscles," and the other on The Relationship Between the Centers of Accommodation and Convergence" In one or the other of these papers you will find a reason for every statement that I shall make In the first place we have two forms of esophoria, true esophoria, dependent on the natural structure of the muscle or its attachment, and pseudo esophoria, dependent on the relationship between the centers of accommodation and convergence Likewise we have two forms of exophoria, a true and a pseudo

In reference to Dr Baker's case, I will say that spasm (in the true sense) of accommodation is always associated with, and dependent on, exophoria, and therefore can be cured by correcting the exophoric condition If the patient is myopic a part of his exophoria—in some cases the whole of it—may be relieved by prescribing a full correction of his myopia, but if the patient is hypermetropic a full correction, or even a partial correction of the focal error will make the patient worse by adding a pseudo exophoria to his true exophoria When the exophoria is as great as in Dr Baker's case, a part of this condition must be relieved by operation In operating on a case of this kind only the exophoria for distance should be corrected, leaving the remaining exophoria in the near to be corrected by rhythmic exercise It is always better to divide the operative effect between the two corresponding muscles It is my practice to operate on one muscle one time only, but I never divide a tendon completely in any form of heterophoria, always leaving a few fibers above and below to prevent the muscle retracting too far Exophoria in emmetropic and in hypermetropic eyes grows worse with advancing years, while an esophoria in such eyes decreases as the patient grows old

Dr LeMond—I have had some experience in the anomalies of refraction, in connection with asthenopia and a want of muscular equilibrium and in trying to establish the same by tenotomies of ocular muscles And I have come to the same conclusion as the old negro who undertook to eat the largest potato in the country, when he said "The more he ate the larger the potato got" So it is with me in regard to muscular anomalies, combined with errors of refraction, the more we cut them and the more attention we pay to the muscles alone, the greater the subject gets on our hands

I think the digestive symptom often plays a very important part in these affections In other parts of the body we might ascertain what existed that was assisting, in a reflex way, in augmenting the ocular anomalies I think the more attention we pay to the whole body, but at the same time not neglecting the eye in our investigation, the more successful we will be I think a great many of these troubles are augmented, very largely, in people suffering from nervous depression and poor digestion in connection with bad hygienic surroundings and the want of proper kind and amount of food

In females, my experience teaches me that these troubles are often associated with uterine troubles of various kinds, which are always ready to act in conjunction in pulling down the system, and so with these complicated ocular troubles, a vade mecum is formed I have quit looking for emmetropic eyes, for I believe that on a close and careful examination that we would not find one eye in one hundred to be in a state of absolute muscular equilibrium

If decided squint is absent, by no means tenotomize the muscles Exercise them with prisms, in a gymnastic sense, say ten or twenty minutes once a day, but do not prescribe prisms for constant use Correct the manifest hyperopia or myopia and the astigmatism, which, I think, you will find in nineteen cases out of twenty If the patient is under thirty years of age I give them 75 per cent of a full correction with glasses, and I think I can safely say that nineteen cases out of twenty, which have come into my hands, have been relieved

Dr J L Thompson—My experience is somewhat like that last given We are indebted to Dr Murrell for the interesting paper and classification I believe there is a very large class of these patients who can be cured, or relieved almost entirely, by the correction of refraction This will include 90 per cent or more of the muscular conditions A number of years ago when I first began practicing I corrected, as far as possible, the muscle errors by means of prisms and would get almost entire relief, and almost invariably on correcting the refractive error the astigmatism particularly would get entire relief In correcting astigmatism alone, I believe relief often comes to the patient There will be a small per cent of these patients who will have to have the muscular anomalies corrected by operation, but the majority yield to correction of refractive errors It is a bad thing to be picking at one muscle so many times I have had patients who wore the prisms for some months and not a particle of insufficiency of the recti muscles existed after two years I do not believe that a partial tenotomy ever benefited a case on this earth, but that all such reported cases would have done just as well without the operation

Dr Gradle—In the heat of discussion on the importance of muscular anomalies it is often overlooked that patients complaining of asthenopia were relieved on the whole about as satisfactorily and perhaps in as large a proportion of cases before the subject of heterophoria was ever brought out It is true that heterophoria is a very common occurrence, but if we examine persons who do not complain of their eyes we find it as well, and often in as high a degree, as in the patients who suffer from asthenopia Such, at least, was my experience as related at the last International Medical Congress Hence before we should admit any causative relation of an observed muscular want of balance, to the complaints of the patient, we should first determine whether the latter are not due to other well recognized causes, and test whether their removal will not obviate the asthenopia On analyzing the conditions which accounted for the asthenopic complaints of 500 consecutive cases in private practice, I found that in 76 per cent hypermetropia, astigmatism or presbyopia were the only and sufficient cause, as proven by the results of their correction, 5 8 per cent were clearly of nasal origin, 4 8 per cent were cured by attending to an existing slight blepharitis, 2 2 per cent depended on slight choroiditis, and in 1 2 per cent the conditions in the eye were connected with progressive myopia There remain 10 per cent not due to these causes, but depending generally on neurasthenia, as manifested as well in other functions In nine-tenths of these, the usual tests showed the muscles practically balanced Only 1 per cent of the total number showed a sufficient muscular anomaly without the apparent causes for the asthenopia, to raise in my mind the question whether the muscular strain were the cause of the subjective symptoms As I could not get any benefit in these patients from temporary exclusion of one eye which necessarily obviates all muscular strain, I did not perform any muscular operations From my own experience I have hence come to the conclusion, that asthenopia dependent upon anomalies of the recti muscles is certainly not a common condition • I can refer moreover to a common observation, which in my mind throws much doubt on the correctness of the prevalent belief in muscular asthenopia The highest degree of heterophoria is that which is not continuously overcome by the muscular effort, but in which at times of fatigue the eye actually deviates These are the cases formerly called latent squint Such patients, however, do not complain of asthenopia, or if they do it is relieved by attention to their refractive condition According to my experience these patients suffer from temporary diplopia, but not from asthenopia or other nervous symptoms

At the request of the Society, Prof Zehender stated, that as far as he is informed, partial tenotomies are not at present performed in Germany At the time when von Graefe first recommended this operation for insufficiency of the interni—as it was then called—it was performed very often by him and other oculists But it was soon learned that a partial tenotomy does not permanently alter the muscular relations, even when the primary effect seemed satisfactory, and that a permanent change could be better secured by a total tenotomy controlled by proper sutures

Dr Risley—I wish to express my gratitude over the conservative tone which has characterized the discussion of these papers In the management of the anomalies of muscular balance it is possible that in some instances too great enthusiasm and inadequate study of the case in hand has led some operators beyond the bounds of prudence Indeed I have already seen the consequences of mistakes in this direction I have under observation a gentleman suffering from incipient tabes, with impaired reflexes, lightning pains, etc, who had nevertheless had his external rectus cut for a supposed exophoria I had another patient with impaired innervation from obscure nuclear disease, which had been overlooked and the externi cut by an enthusiastic surgeon, this, too, when a careful study of the relative strength of the muscles had shown but 6 degrees of abduction and 2 degrees of adduction Fortunately no great harm could result under such conditions, but such instances demonstrate the necessity for great caution, lest the early symptoms of a nuclear palsy, or the incipient stage of tabes, which so frequently declares itself in transient ocular symptoms, should be mistaken for so called heterophoria

When attention was first called to this subject in its most modern phase, I could but wonder how I had succeeded in relieving so many people of their asthenopia, being unmindful of the reputed frequency of these anomalies of the vertical muscles and in a measure also of the external rectus A more careful study of those persons who had not experienced entire relief from correcting glasses and careful attention to general health, soon convinced me that in a certain number of cases the trouble was due to some form of muscular anomaly Within a few years I have succeeded, either by carefully adjusted prisms or by tenotomy, in greatly relieving a large number of my former patients and others Therefore while mistakes may have occurred and inordinate claims for the efficacy of tenotomy in curing diseases of the general nervous system may have been made, still I am sure there is too much of truth in these claims, and too much of real value in the careful study and treatment of heterophoria to relegate the whole subject to the realm of charlatanism

Dr Baker—I do not wish to convey the idea that there is nothing to be gained in the operations for heterophoria, in fact I make them, and possibly as often as any one here, (but not as often as some of my neighbors whom a friend of mine calls "post-graduate friends") and get good results in most cases The point I wish to make is this which are the operative cases? Not such a case as this a patient came to my office some time ago in whom a so-called oculist had proposed an operation for heterophoria, and yet the patient had one and one half D of hypermetropia which had not been corrected I gave him a pair of spectacles and his muscular insufficiency disappeared together with all asthenopic symptoms

The muscular insufficiency in this case was caused by the error of refraction, as I believe it to be in ninety nine cases out of a hundred In nineteen cases out of twenty, if we correct the refractive error we will give comfort to our patients In all, I prescribe lenses that fully correct the error of refraction and tell the patient to wear them a certain length of time, and if the symptoms of asthenopia do not disappear I then correct with prisms, muscular exercise or by an operation

Dr Murrell—I believe that this subject of muscle errors is very imperfectly understood by the majority of men in our profession I confess I knew nothing of muscle errors until within the last year I am just beginning to see light, that there is something in it there is no doubt I take a very conservative view of this subject of operation I have had patients bring their glasses back and object to taking them because they did not give entire satisfaction Until I began to search for these muscle errors I could not find what the cause of complaint was I have prescribed prisms in a number of cases lately, giving complete relief in a large portion When a patient comes to me I first correct the refractive error, and then correct the muscle error by prisms, and if this fails to give relief I perform a tenotomy Dr Savage has devised means by which we can exercise the ocular muscles, and thereby develop them The character of exercise set forth by him in a recent publication is rhythmic and must, in all cases, stop short of fatigue

The First Woman M D—Mrs Elizabeth Blackwell was the first woman in the Republic to receive the degree of M D, a fact which is once more brought into notice by the accounts of the death of her sister in-law, Mrs Lucy Stone

SOME REMARKS ON SQUINT AND ITS TREATMENT

Read in the Section on Ophthalmology, at the Forty fourth Annual Meeting of the American Medical Association

BY J H THOMPSON, M D
KANSAS CITY, MO

To all observing ophthalmic surgeons it is evident that the common operation for converging squint is by no means perfected, and, I am inclined to think that many of my hearers are willing to join me in the belief, that, of all the operations on the eye, excepting perhaps iridectomy in acute inflammatory glaucoma, that for squint is the most difficult, and yet, there is scarcely a traveling quack or recent post-graduate enthusiast who will not tenotomize a rectus muscle, at any time, on any patient, and for any fee Some years ago I was regretting the difficulties in this operation in the company of some of the members of this section, when I was astonished to learn that, for some ophthalmic surgeons the correction of strabismus was child's play and almost beneath the dignity of an eye clinic Why is this? Because in childhood it is very easy to straighten an eye, and the immediate effect is brilliant, but in a very large majority of cases the more satisfactory the primary operation, the more disastious the remote consequences, at least, that has been my experience, not only in my own cases, but also in the cases of other operators, many of them excellent men Therefore, I take it, a short paper on this subject will not be out of place

I am much inclined to think that many people never acquire binocular vision, the visual apparatus being defective either in a want of commissural fibers between the two visual centers, or an abnormal relationship between these centers and the psychical areas in the cerebral cortex It requires no greater stretch of the imagination to believe this, than to say that Daltonism depends upon a deficiency of certain color fibers in the optic nerve or brain I do not mean that there is an antipathy to single vision, but that single vision is impossible, because of the inability of the individual to join the two cerebral pictures Thus if binocular vision is not acquired, *diplopia is a natural* condition and does not lead to any embarrassment of sight, because the condition can not possibly be compared to binocular sight, of which the subject has no conception

Not many days ago I examined a man 30 years old He had alternating converging strabismus, in each eye tested separately, his vision was 20 18, he would use either eye, if he looked at an object to the left of the vertical plane, he would use the left eye and squint the right, if to the right of that plane, he would use the right eye and turn the left No combination of prisms or colored glasses could excite diplopia The man was hyperopic 2, 5 D In this case the individual suppressed the visual field of the eye not in use at the time as is evidently the case in birds and fishes I have seen the same in young children with beginning squint

Although there are reasonable doubts of the truth of this idea, it can not be denied that some children are born with defective vision in one eye This congenital amblyopia will be discovered, if sought for, in very many, I may say the majority of children with beginning squint at a time of life when it can not be reasonably supposed that the partial blindness is the result of disuse I have found this defect even in periodic squint, and in my experience it is so common that I consider it the rule rather than the exception, and that it is the predisposing cause of squint in many cases That hyperopia is an exciting cause is evidently true, but we all know that young hypermetropes can overcome a high degree of refractive error without fatigue of the ciliary muscle, and are seldom called upon to assist accommodation by convergence Hypermetropia even when combined with monocular amblyopia is hardly sufficient in itself to cause strabismus, because if we render the eye emmetropic with glasses, even at the time of periodic squint, there is no certainty that the deformity will disappear, and although some writers insist on such conservative treatment, the results are not satisfactory I have tried it and I have not yet found the method successful It is for this reason that there are some doubts of the correctness of Donder's teaching

What relation the angle Y has to strabismus convergens and the influence the superior and inferior recti muscles have over squint is not fully determined, but it does seem to me that often the external recti muscles are not able to hold the optic axes parallel, especially since we know that the center of rotation lies outside of the vertical muscular plane, or the plane of the superior and inferior recti muscles

This may in some persons be overcome, as in adults we find a high degree of prism can be borne in time, while in the beginning small angles excite diplopia If from a high angle Y, or increased accommodative tension of the interni, the externi are fatigued, the eye tends to turn in, the child preferring monocular vision in comfort to binocular sight with pain Again, there is another tendency to latent convergence, and that is that the center of rotation lies on the outside of the plane of the superior and inferior recti muscles In health the tendency to rotate inwards is balanced by the action of the obliqui, so if from any cause, nuclear perhaps these muscles fail in their duty, the external recti fatigue, give way, and squint results

At an early date in my professional career, I felt convinced that it was not alone the tension of the internal recti muscles which held the eyes turned inwards in confirmed squint I thought then, as I do now, that all the muscles which rotated the eye inwards played an important part, for it does not seem reasonable that a secondary contracture should alone attack the interni and leave the superior and inferior recti muscles intact It is safe to consider that these two muscles are involved also in the pathological changes which go so far to hold the eyes crossed It is only another step in advance to affirm that all the structures in the orbit, immediately surrounding the eye have altered their relationship to correspond to the false position of the eyeball, and of all such structures the capsule plays the most important part

From the above, it is evident that the operation for squint is by no means such a simple procedure as many would wish us to believe, and that when a surgeon undertakes to correct the optic axes, he has a case before him which may require for its successful issue a most critical examination into its cause, a careful study of its condition and a most minute dosage in any operation that may be undertaken As I have said before, it is not difficult to straighten the eyes, but it is difficult to guard against failure, since the eyes may turn in again, or in time go out the other way The conservative treatment advanced by our confrere, Dr Ayres, has many supporters throughout the United States It can not be denied that the continued wearing of glasses may cure some cases, but if I am not mistaken, the method is less satisfactory than the surgical means at our command It has this advantage, however, it can be tried at a time of life when all operative procedures are to be condemned I am not in favor of prescribing glasses for very young children, and I always feel when I see a baby in spectacles that theory has run off with common sense

In squint depending upon simple hyperopia, when the vision of both eyes is good, binocular vision may be secured by a simple tenotomy and the wearing of correcting classes, providing the patient is less than thirteen years old and more than seven For reasons well understood, in making a simple tenotomy the operation should be divided between the two eyes, and the cutting of the capsule should be in proportion to the degree of convergence Stevens' method of modified tenotomy has immensely simplified this operation and makes it possible to accurately gauge the effect Some of us are in favor of rotating the eye outward with a stitch, but I am afraid that this stitch has done more harm than good, for between the eighth and thirteenth year the stitch is rarely necessary, and if the operation is made on one eye at a time for full correction, it is positively harmful I think it is better to under correct than over correct, for I see no objection to a second operation, or indeed a third, while insufficiency of convergence is to be deplored, downright divergence is shameful

In cases where there is no hope that binocular vision can be attained, either because of well marked monocular amblyopia, or other causes, I believe it is best to combine tenotomy with advancement, which should be always capsular with or without division of the external tendon This operation should not be undertaken on a patient under thirteen or fourteen years old Why I favor advancement of the capsule is for the following reasons in long confirmed squint we usually have contracture of the internal recti and other adductor muscles, together with stretching of the externi This muscle is therefore relatively weak and may not be able, unsupported, to overcome the tendency of the eye to roll inwards, even after the tense structures are cut So, there is danger that the muscle is advanced too much and that the capsule on the inner side of the eye is too extensively divided Therefore to divert the eye with a limited tendo-capsulotomy requires too much pulling on the part of the advanced muscle, and after the stitches are removed, the new formed adhesive tissue may give way To advance a muscle requires considerable dissecting, pulling with forceps and tearing with hooks, which add greatly to the possibility of infection, and since it is advisable to do this work without a general anesthetic, using cocain alone, the operation may be unduly painful

In old cases of squint after the thirteenth year, I advance the muscle with the capsule, either operating on one eye and dividing the internal recti of both, or tenotomizing and advancing on both eyes This operation has always been successful in my hands and I have not been compelled to try any one of the many methods suggested by authors or extolled by pamphleteers

The reason why I like this operation, whether the tendon be cut or doubled up as suggested by De Wecker, is that the relation of the tendon to the capsule is not disturbed, and the adhesive inflammation consequent to a rather extensive wound of the capsule and conjunctiva binds the parts so tightly to their new position, that there is no danger of their giving way, even when the stitches are removed on the third day Some may fear that the tension on the threads in this operation may tear them away, but since I make my stitches above and below the cornea, passing a flat needle through the episcleral tissue and perhaps the superficial layers of the sclera itself I have not known that to happen I endeavor to place the stitches so that the converging superficial threads when tied make tangents with the cornea and do not touch its epithelial surface, avoiding irritation if not ulceration I prefer a waxed thread, and when about to tie the muscle forward, I twist the corneal threads so that the point of convergence marks the position of the knot, thus accurately dosing the degree of advancement and foretelling any injury to the cornea after the knot is tied

DR SAVAGE—In order not to kill time I will make a few statements, and for the reasons on which these statements are founded I must again refer you to the last issue of my journal One of two things must always be at the bottom of internal squint, viz intrinsic esophoria and pseudo esophoria In most cases the two coexist Other conditions, such as a corneal scar or an amblyopia are often associated with these causes Hypermetropia, the cause of pseudo-exophoria, nearly always is found in cases of internal squint True esophoria is rarely so great that the guiding sensation can not restrain it, but when a pseudo esophoria is grafted into it, the two combined throw off the mastery of the guiding sensation and there results a *turning* where before there was only a *tendency* The two forms of esophoria may be restrained by the guiding sensation for a long while (in most cases for a lifetime) when something disturbs the nerve centers and the esotropia occurs, the guiding sensation having lost its control In all cases of internal squint the first thing to be thought of is the destruction of the pseudo-esophoria This is readily effected by a mydriatic, the first effect of which, however, is to increase the squint by increasing the pseudo-esophoria The pseudo esophoria having been cured in this way, the true esophoria may be again brought under the control of the guiding sensation, the eye swinging itself suddenly or by degrees into line In very young children the mydriatic is often enough to effect the straightening of the eyes In older children the hypermetropia should always be corrected to the fullest

The correcting lenses unaided by the mydriatic, in some cases will cure the squint by removing the pseudo esophoria, but in many cases the mydriatic must be made to aid the lenses because of a disposition, continued for a longer or shorter time, on the part of the eyes to cross when an attempt is made to fix on the near point When squint is thus cured there always remains the true esophoria which at some time may have to be treated either by rhythmic exercise or partial tenotomies But the great majority of these cases of internal squint are brought for treatment at a time when mydriatics and lenses can not effect a cure The balance must be done by tenotomies, complete when necessary partial when possible In all these cases the fully correcting convex lenses should first be determined, and an estimate be made as to how much of the condition they will relieve Then as little cutting of tendon and capsule should be done as possible

Dr J L Thompson—I had a patient a little child only three months old, who had strabismus in one eye only By using the atropin I straightened her eyes I have had patients where the eyes turned in a good deal, in which I have used the mydriatic and glasses as early as the eighteenth month, who were very much benefited In other patients I have operated on the muscle and have had success In a certain number of cases we will never be successful by all the operative measures that have ever been devised The only thing to do in these cases is to watch them You will operate on a patient, getting beautiful results and ten years later you will have something that will not suit you at all—the eye turns the other way These patients we feel like sliding on some one more sanguine as to results We had better never have had anything to do with them Concerning the question of amblyopia, I will say that I am satisfied that there are numerous cases where there is more than heterophoria that causes strabismus

Dr Hotz—I agree with the main statements of the author, and wish to make only a few remarks on the subject of advancing the muscle, inasmuch as I prefer the resection to the advancement of the weak muscle I divide the tendon of the muscle, leaving a short stump at the line of insertion, then cut off a piece of the tendon, in proportion to the degree of convergence, and attach the muscle to its original place by stitching it to the stump We gain several points by this method in the first place we can gauge the effect to a certain extent by the size of the resection, we are sure we have a firm hold for our stitches, and they will not slip as they are so apt to do when they are run under the conjunctiva only, we furthermore know that the muscle will be held to the eyeball in exactly the same line that it was originally attached But whether we do advancement or resection the operation should always be accompanied by the tenotomy of the contracted internal rectus muscle

Dr LeMond—If we were all of one mind in this department and never differing with each other, it is quite likely that ophthalmology would never have reached the stage of perfection and exactness that it enjoys to-day, but I must say that atropia in my hands has not been satisfactory, in fact, I rarely ever use atropia in connection with these kind of cases In 98 per cent of the cases of squint I have operated on in the last year (about fifty cases) I have had a decidedly unsatisfactory result in one case I invariably find in these cases a vast amount of hypermetropia, and I really believe that in nearly all of these cases of squinting eye hypermetropia is at the bottom of it After the operation I correct the error of refraction and tell these patients that they will have to wear glasses from six to twelve months perhaps, but likely by that time they will be able to go and see comfortably without them This course of treatment, with me, has been very satisfactory In two cases I had to use the stitch to hold the eye in situ I only do this where a complete tenotomy of the muscle has failed to put the eye on the same visual axes with its fellow I prefer using the stitch to doing repeated tenotomies I think the amblyopic condition is due largely to a great amount of hypermetropia In my experience I have found the amblyopia confined to the squinting eye I believe whenever we look more carefully to the eyes of school children the less squinting we will have simply by applying the needed remedy, that of prescribing glasses Statistics show that the Germans double and treble us in the number of glasses worn, according to the same given number of population I think this proves to us, very conclusively, that they are just that much ahead of us in finding the early errors in refraction and correcting them

Dr Gibson—I want to make one remark only, in favor of the advancement that has been spoken of It does away with that protrusion of the eyeball which we have as a result of a simple tenotomy That I think a very essential thing to take into consideration I have seen this protrusion quite marked in some simple tenotomy operations Combined tenotomy and advancement certainly gives better results

Dr Risley—Do you measure the adduction by the image of light on the cornea?

Dr Thompson—Yes, sir

Dr Thompson—I am much pleased with the interesting debate on my paper regarding the amblyopia of squint I have been surprised to find in children two or three years old, the bad vision in the deviating eye, when that eye had only squinted a few days, certainly not long enough for the sight to fail from disuse From such experience and from the tone of some ophthalmic writers I am inclined to think there is a great deal of doubt about the truth of amblyopia exanopsia Children born with cataract and successfully operated upon some years afterwards do not as a rule show up blindness If the effect of disuse be true in one class of cases, why not true in the other? The use of atropia in children for the correction of squint is not so far as I have been able to observe satisfactory I have tried it for months and do not know that I ever succeeded If the squint is entirely due to hypermetropia I think it may be overcome by glasses Indeed all such methods should be tried before resorting to an operation I have relieved squint in boys of 15 and 16 years of age by correcting the hypermetropia, for when the glasses were taken off the squint would return I have never seen a case of strabismus corrected in a young child by operation but that when the subject grew to be 15 or 16 years old there was loss of convergence or direct divergence I have operated on children and got the most magnificent results, but when they grew up to adult age I was ashamed of them and myself too

---

EXOSTOSIS OF THE ORBIT

Read before the Section on Ophthalmology at the Forty fourth Annual Meeting of the American Medical Association at Milwaukee

BY ROBERT FIELDS LE MOND, A M, M D

PROFESSOR OF DISEASES OF THE EYE AND EAR IN GROSS MEDICAL COLLEGE DENVER COLORADO

When I received a letter last fall from the president of the ophthalmic section of this distinguished body, requesting me to contribute a paper on this occasion, I immediately began to cast about for a subject upon which to write In the selection of a subject I had three objects in view, viz

1 One in which great need existed for its further development to a more successful and satisfactory termination, both to the physician and patient

2 One in which there was sufficient gravity to claim the attention, interest and hearty cooperation of every ophthalmic surgeon present

3 One in which I very much needed to be enlightened upon, myself, for I believe it was Archimedes who said "If you desire wisdom, acknowledge your ignorance that your teachers may know where to begin"

I therefore present to you, the great godhead of ophthalmology, the subject, "Exostosis of the Orbit," a morbid condition which has successfully baffled the best skill that is known either in medicine or surgery to-day, because statistics show that over 60 per cent of the cases which have been reported have succumbed, either to septic meningitis or pressure upon the brain following the operation, and it is our duty, as benefactors of the human race, to make a great and united effort to overcome any evil which is claiming victims among our kind at the rate of from sixty to seventy out of every one hundred it attacks

I think it is generally accepted as a fact by most writers upon the subject that three forms of exostosis exist 1, the cellular, 2, the craggy or semi-cartilaginous, 3, the ivory

The cellular exostosis is characterized by its being composed of an osseous crust, which surrounds a rather soft substance that is thoroughly supplied with a bony framework resembling the honey-comb somewhat, and it is thought originates from the periosteum This form of exostosis rarely ever attains any great size and is disagreeable only on account of its cosmetic effects, as it never gives pain unless interrupted by a blow or pressed unnecessarily

The semi-cartilaginous, or craggy form of exostosis, is composed of layers of craggy bone often interlaced with cartilaginous particles, as well as surrounded entirely by cartilage, and particles of periosteum may be traced about the tumor, but it does not make a complete covering and is found in patches only This form of exostosis is more apt to attain a greater size than the cellular, it offers but little resistance to the surgeon and usually makes a good recovery Many cases have, however, been reported which proved fatal, but it does not compare in point of mortality with the third class of exostosis, which I will now describe

The third class is the ivory exostosis, which is by far the most formidable of all the osteomata yet described by any writer upon the subject It is excessively hard and consists of perfectly developed, and very fine bone tissues According to McKenzie, it originates in the diploe, presses the compact tissue of the bone before it, and forms a round, smooth and somewhat nodulated tumor There appears to be one general characteristic of this growth, and that is, it seems to have an affinity for extending into the brain Most cases which I have seen reported, in which an autopsy was held, show that the intracranial division was developed more rapidly than the outside portion

Regarding the etiology of exostosis of the orbit, comparatively little is definitely known It often supervenes upon periostitis or ostitis, and is thought by a number of writers to be of syphilitic diathesis, as a positive knowledge of syphilitic complications has been shown in a number of cases reported Other cases have been known to have received blows about the eyes which have been given the credit of the exostosis, while still other cases have received falls of various kinds, ranging from early childhood up to 25 or 30 years of age, and a number of cases have been found to have fractures of the bones of the orbit As, however, this disease appears about equally divided between the sexes I think the theory of falls and blows plays but a small part, for what boy has not fallen times beyond mention and narrowly escaped death, time after time, from blows of various kinds and intensities? They would not be boys were not this the case, so I think this practically excludes one of the prominent causes referred to by most writers Again, it is thought by others, that the osteoma is due to a diseased condition of the frontal or ethmoid bone, or of the frontal sinus, and that the parts mentioned are possibly wanting in some of their elements Others, again, advance the idea that it is possibly due to digestive disturbance or a want of proper assimilation and appropriation of the elements of food matter, that the superabundance of alkalin reaction being present, the system is filled with bony material and thereby develops the osteoma in seeking an outlet

These osseous tumors are usually very hard to the touch, showing, even at an early stage, a remarkable amount of resistance They are usually slow in their development and it is something unusual for any pain or inflammatory action to be present, though in a few exceptional cases much pain has been experienced

The degree of exophthalmus, impairment of vision, rotation, and general movement of the eyeball will, of course, be entirely dependent upon the extent and situation of the exostosis

According to the best authorities, in the early stages of this trouble the treatment should be the promotion of all means of absorption by the internal administration of pot iodid, and a thorough saturation of the tumor locally with mercurial ointments The patients' general health should be looked after closely and not allowed to become depleted or run down, they should be supported by good, generous diet, and encouraged to travel or reside in the country If the tumor is small and giving no special inconvenience and appears to be merely existing without any apparent activity, it should not be disturbed but quietly let alone But when we find by watching the case for a time that the osteoma is gaining on us, I think the surgeon should not hesitate to advise an operation at once

A very large per cent of exostosis occurs in persons under twenty-four years of age In some cases it has been discovered in babes as young as one or two months old, and in one case was found to exist at birth But a large majority occurs between the ages of ten and twenty years, and attacks about one out of every thirty thousand cases of eye trouble Bornhaupt collected eleven cases of exostosis of the orbit which were operated upon, and out of that number, seven died of septic meningitis (63 per cent), two cases recovered, and two were lost sight of and the final results of these operations were never obtained Berger and Tryman collected nine cases which were operated upon, six of whom died (66 per cent)

The mortality does not appear to vary to any great extent in all the collected reports I have been able to examine, from the recorded experience of some one hundred authors in this department of surgery, the average mortality will be some 65 per cent I thought it best to be brief and not weary you with tabulated reports, and will now go on to describe a very unique case which was referred to me recently by Prof W H Davis of Denver

Mr R, aged 24, a very large and well-proportioned man weighing 190 pounds complained of double vision and a blurring of the right eye, in addition to the above symptoms there was also quite an enlargement on the lower orbital bone of the same eye, it was continuous with the lower orbital bone throughout its whole extent It also extended upward nearly three quarters of an inch, and backward continuous with the floor of the orbit to near the optic foramen, the enlargement at this time was about the size of a pullet egg He had quite an exophthalmus which pointed upward and outward The line of vision in the right eye was at an angle of about 35 degrees from that of the left eye. There was little or no inflammatory action present, nor had there been at any time since the beginning of the enlargement, which the patient said was about twelve months before. He said it had never given him pain, or troubled him in any way except by causing the defect in vision and a continuous diplopia. His vision in the right eye, at this time was 7-20. He was raised on a Missouri farm, and gave an excellent family history, having never had any serious sickness in his life. His parents were both living, as well as several brothers and sisters.

The ophthalmoscopic examination showed no organic change, but there was a slight tortuosity of the blood vessels of the retina. There was positively no tuberculous or syphilitic diathesis in this patient's family history. I had him visit my office continuously for several days until I was thoroughly satisfied that my diagnosis was correct. I told him that I was sure that, at the past rate of the development of the tumor, we would very soon be forced to do one of two things: chisel off this bony mass which was encroaching so rapidly upon the eyeball, or perform enucleation. After advising with some of the members of his family who had accompanied him to Denver, he decided upon the former, and on the 17th of December, 1892, I performed the operation with the assistance of Dr. Coover.

The patient being completely anesthetized, I made a horizontal incision, commencing about six lines below the internal canthus and extended it to a little beyond the external canthus, cutting entirely through the integument down to the periosteum. I then dissected the flap up, until it could be laid back upon the superior orbital bone, which was held by my assistant. I then dissected up the periosteum and began chiseling into this bony mass, and I very soon concluded that I was pretty much in the same condition as the old pioneer, who wished for some one to help him turn the wildcat loose, as I could see by the way it completely annihilated the edges of all my chisels that I had a hard job on my hands. I took a very small chisel and succeeded in drilling several small holes into this bony mass, then by means of bone pliers connected these holes, which gave me a leverage, by which I was enabled to pry off a number of pieces, thereby reducing this bony mass about two-thirds of its size. I then attempted to pry another piece out of the floor of the orbit, knowing that it would add very much to the utility of the eye, but in this effort I was completely foiled, as it was so unyielding that I felt if I brought to bear any more weight on my pliers I should certainly burst through, and possibly put my patient in a condition to need an undertaker instead of a physician. So we decided that it was wisest to proceed no further, as we felt that the operation so far would be in a measure successful, having reduced the tumor at least two-thirds of its size. I then dressed the wound antiseptically, using a bichlorid of mercury solution, 1-5000, about as hot as it was comfortable to bear, giving the wound a thorough drenching. I then drew the flap down and bound it in its former position with about half a dozen stitches, then bandaged his eye, ordering the nurse under no circumstances to disturb the bandage until I saw the patient the next day. The patient rested very well that night, and felt fairly comfortable the next day. There was quite an inflammatory reaction of course, but this soon subsided and the healing process went steadily on to complete recovery, leaving scarcely any scar. After seeing him every day for about one week, I dismissed him, telling him, however, to call occasionally and let me see how he got along. He visited me occasionally for about one month. By this time there was comparatively slight variance in the eye from its fellow, the diplopia was completely gone and his vision measured 20/30 in his right eye, and believing that I could render him no further assistance, I dismissed him finally, feeling that I had every occasion to be thoroughly satisfied with the result obtained.

Dr. Knapp.—This is certainly a disease which is extremely important. The majority of these tumors are in the upper-inner part of the orbit, and spring from the frontal sinus. A goodly number are on the nasal side of the orbit and originate in the ethmoid. I had a patient on whom I operated for a tumor of this kind four hours, and got out only a small portion of the tumor itself. That man had attacks of meningitis and died eleven weeks after the operation. The tumor formed in the frontal sinus and penetrated into the skull. Such cases you see in large pathological museums, especially those in London. Hence the former advice: leave these tumors alone. I operated on a gentleman, age 44, about thirteen years ago. The tumor was larger than a walnut. I got it out by the method which Maisonneuve followed in removing a large intranasal osteoma, viz.: by subperiosteal enucleation. It took me a whole hour. The patient made a rapid recovery without suppuration. He is living, healthy, and no one now could discover from which orbit the tumor had been removed. The method is essentially followed in the removal of all growths, not by attacking and removing them piecemeal, but by shelling them out from the neighboring sound tissue. It has done me good service, particularly in cases of ivory exostosis of the orbit and the external ear canal.

Dr. Jackson.—The case I reported last year has continued well, so far as I know. In that case I think it was a necessity, in order to remove it without enucleating the eye, to divide the tumor before trying to take it out. It was of excessive hardness, but after breaking several instruments I found that it could be pierced by a hand drill.

Dr. Allport.—In this connection, I would say that I had a case of exostosis of the meatus some time ago that I successfully removed with the dental engine, not with the drill, however, but with some sharp burrs. The burrs became dulled occasionally during the operation, and had to be replaced by others that were new and sharp. I simply commenced burring at the apex of the tumor, and continued smoothing away the growth until the level of the meatus was reached. I have also used the dental engine in the same way, in some mastoid operations, and consider it an excellent method of operating when the burr is used and the bone substance gradually thinned away until a generous opening is produced. It is much safer than either the mastoid drill or chisel for obvious reasons.

Dr. LeMond.—We are very much pleased to have Prof. Knapp present with us and I feel complimented to have him discuss my paper. As I went over carefully his recorded experience I found it more extensive than any surgeon's in the United States on exostosis of the orbit. I am very much pleased to have heard what he had to say. In the last few months I have done two operations for exostosis of the external auditory canal. I had begun to think that perhaps I had better change my title and set up altogether for diseases of this character. I did both of these operations by means of a dental engine and a small chisel. One of these cases, a gentleman 36 years old, told me this exostosis had been forming for about five years. It had completely occluded the external auditory canal and rendered it almost impossible for the ceruminous discharge to be removed I took pieces of this bone to a professor of pathology and had it examined, but it was found to be nothing but the ivory character of the exostosis

I beg pardon, Mr President, for having digressed in mentioning the exostosis of the external auditory canal, and would not have done so had not one of the gentlemen, in discussing my paper, introduced the subject I was glad, however, the gentleman referred to it because it is a subject in which I am very much interested, and more especially at this meeting was I anxious to hear it discussed, from the fact of its being such a rare affection that it is a hard matter to get information regarding its characteristics I have enjoyed the discussions of this hour, and was anxious to be enlightened upon this rare field of surgery

I desire to thank Prof Knapp, especially for the kindly manner in which he handled my paper

OPTIC NERVE TROUBLES ACCOMPANYING OR FOLLOWING FEVERS, ESPECIALLY TYPHOID FEVER

Read in the Section on Ophthalmology at the Forty fourth Annual Meeting of the American Medical Association

BY JOSEPH A WHITE, A M , M D
RICHMOND VA

I must apologize in advance for the paper I here present to this section, but I do so because I want to awaken a discussion on a subject in which I am deeply interested, and may thus be a poor means of obtaining a good result, on the somewhat equivocal ground that 'the end justifies the means" In my experience I have met with many cases of optic nerve atrophy that followed so closely on typhoid and other fevers, that there is every probability they were the result of the pathological conditions attending these diseases Whether they commenced as optic neuritis, which could be ophthalmoscopically demonstrated, or whether they followed on post ocular alterations in the optic nerve without ophthalmoscopic symptoms could not be determined But in all probability there was neuritis, or compression with or without papillitis, followed by atrophy

We all know how difficult it is to settle a question of this kind, without regular systematic investigation, by examining a series of such cases during the attack of fever Post febrile amblyopia or optic nerve atrophy might be due to brain complications, or to general systematic exhaustion following the disease, or more rarely to excessive use of quinin in treating some fevers But may they not also be the result of neuritis, or of compression of the nerve due to the pathological alterations brought about by the specific virus of such diseases as measles, scarlet, typhus, typhoid, malarial and other fevers? If this should be true, would not an early recognition of the eye trouble save, by prompt treatment, many an eye that would otherwise be lost? It has not been very long back, that so little attention was given to the ear trouble accompanying scarlet fever that many a person lost hearing or life or both as the result of this oversight Has not the investigation and teaching of the aurist on this subject been productive of great good, saving many a person's hearing, and life as well?

That text-books say little or nothing about optic nerve troubles accompanying or following fevers, that the literature on the subject is very meager, proves nothing, except that no one has investigated it systematically or scientifically It only shows that this is one of many open fields for research that may repay the labor More eyes are lost from atrophy after febrile affections than one would suppose from reading the available literature about this matter There are few of us who have not seen such cases

In looking up the subject, I wrote a few lines to about thirty ophthalmic surgeons scattered over the country east of the Rocky Mountains, asking their experience and enclosing an addressed envelope for a reply Twenty-two of them sent in a prompt and courteous answer, six (Drs Knapp, Burnett, Noyes, H W Williams, Gradle and Savage) said they had little or no experience in optic nerve troubles in cases of fever, one (Dr Calhoun), that he could not recall his cases of this nature, but was satisfied his record book would show he had met with them, Another (Dr Hotz), that his record would show cases of neuritis and atrophy, supposed to have been due to typhoid fever, although he did not consider such cases valuable for statistics Dr Risley wrote that he had seen cases of atrophy following spells of continued fever diagnosticated as typhoid, and also one case of neuritis after measles, Dr J L Thompson has observed atrophy of the optic nerve following typhoid fever, Dr Ed Jackson wrote that he had seen cases of post-neuritic atrophy ascribed to typhoid fever, but careful questioning as to symptoms gave him the impression that the cases were either cerebro spinal meningitis, or typhoid fever complicated with meningitis, Dr L Kipp has met with cases of atrophy after typhoid

Dr Michel said the cases of optic neuritis seen following so called typhoid fever were more probably due to meningitis, Dr Charles Stedman Bull wrote that he had observed many cases of optic nerve trouble in fevers, but had not time to go over his cases in detail, Dr Oliver wrote me nearly the same thing as Dr Bull, but said he would send me notes of his cases, Dr L Connor has never seen neuritis, but has seen atrophy ascribed to typhoid fever and which was probably the result of the pathological conditions that obtain in the fever, Dr Eugene Smith has had several cases of atrophy after fever, but never had a chance to examine a case during the attack, Dr de Schweinitz has seen one case of slight superficial optic neuritis in connection with malarial fever In another case with double optic neuritis in a colored girl supposed to have typhoid fever, the autopsy revealed tubercles in the meningitis, and the meningitis was probably responsible for the neuritis In two other cases he has seen choroiditis and secondary atrophy of the optic nerve after typhoid fever, Dr P D Keyser has seen very few cases of optic nerve trouble after typhoid fevers, but has met with atrophy after typhus Dr Alt has never seen real and lasting atrophy following fever alone, Dr Samuel Theobold has never seen pure optic neuritis following typhoid fever or malarial fever, but has notes of a case of choroido retinitis (and probably neuritis but the media were too cloudy to determine this point) which developed on the seventh day of a severe case of typhoid fever in a child who died three days after the eye symptoms were manifested, Dr Wurdeman has seen cases of optic neuritis as a result of typhoid, scarlet and other fevers where there has been meningeal complications, and they were followed by more or less atrophic degeneration A remarkable exception to this experience was a case of cerebro spinal meningitis, which became perfectly blind and showed symptoms of optic atrophy in November, 1892, yet in January 1893, began to recover vision and by the end of March it was entirely restored

Now this consensus of opinion goes to show that optic nerve troubles accompanying or following fevers are commoner than supposed Foerster (in Graefe-Saemisch) speaks of atrophy of one or both nerves following typhoid fever, Gowers (Medical Ophthalmos p 279) says "Loss of sight has been many times observed during convalescence from typhus or typhoid fever, and subsequently atrophy of one or both nerves In some cases when the eye affection was early observed optic neuritis was found Commencing atrophy may be observed without proceeding inflammation, or double neuritis may be present," Hutchinson (Ophthal Hosp Rep ix p 125) recorded the case of a boy whose sight failed after a fever with typhoid symptoms, and of a sister with a similar condition Symmetrical neuritis was found in both, Dr Stephenson recorded (Transact Ophthal Soc Vol viii 1888, p 250) a case of double optic neuritis after measles, when there had been no sign of meningitis, Dr Wadsworth (Trans Ophthal Soc 1880, p 125) has recorded some interesting cases after measles, Betke, Phlueger and others have observed neuro-retinitis in scarlet fever

Loring (Textbook of Ophthal Vol ii p 203) speaks of neuritis in connection with typhus, typhoid and other febrile disturbances But adds that when it occurs in cases of fever, especially where there is delirium, that there is reason to believe there is meningitis with the fever This statement, however, does not accord with the known pathology of typhus, typhoid and most other febrile affections Meningitis is a very rare complication Sir Wm Jenner never saw it in typhoid fever According to Osler in the 2,000 Munich cases it was only observed eleven times Head symptoms are not always a sign of it We can have delirium without meningitis Arteritis with embolism is oftener found, and thrombosis still more frequently

On account of the rarity of meningeal complications in typhoid fever, and still seeking to make meningitis responsible for the neuritis, both Leber and Stellwag Von Carion suggest that when neuritis is present, cases of meningitis have been confounded with typhoid There is no necessity to look for meningitis to explain the presence of optic neuritis or optic nerve compression with or without papillitis, because in nearly all cases of typhoid there is more or less cerebral congestion with serous effusion into the arachnoid cavity, lateral ventricles and subarachnoid space, sufficient explanation, on Schmidt's or Parinaud's theory, of optic nerve changes Moreover it is well known that neuritis may occur as an idiopathic affection, with great obscurity as to causation, unless we can refer it to some vasomotor disturbance

In this connection, allow me to present three cases from my record book, all of which may be of interest

1 A case of optic neuritis after typhoid fever that recovered

2 A case of atrophy after typhoid that has steadily improved under treatment

3 A case of perfect blindness after malarial fever which recovered perfect vision

Case 1—Miss E W, called to see me in September, 1885, complaining of absolute inability to use her eyes She was just recovering from an attack of typhoid fever which was of short duration, was not very severe in type and not attended by any marked head symptoms Accompanying the difficulty of vision there was considerable photophobia Examination showed marked neuritis The swelling of the nerve measured one dioptric I attributed neuritis to the effect of the pathological alterations in typhoid fever I put her on iodid and bromid of potash, used dry cups to the temples because her health had not been entirely restored I saw her occasionally during October, November and December Her treatment during this time was directed to building up her general health and getting rid of any inflammatory changes about the optic nerve and the papilla At first she made such little headway towards recovery that I feared optic nerve troubled might be followed by atrophy, but she began to improve, although she had not recovered entirely when she left me in December

In October, or a month or so after she came under my treatment, her family were so much worried about her condition that I proposed a consultation, and their family physician selected an oculist in another city, who was a well-known member of the Ophthalmological Society, and without any suggestions on my part, or without being aware of my diagnosis, he came to exactly the same conclusion, that it was a case of neuritis with considerable swelling about the papilla She left Richmond in the early part of 1886, and in March of that year called to see me, and stated that she had been entirely relieved, simply by the adaptation of glasses fitted by an oculist whom she consulted and who told her that she not only had no neuritis then, but that she never had had any That the trouble was entirely due to the astigmatism, and would disappear, and there would be no return of it if she wore her glasses I examined her and found that she had no trace of neuritis remaining, it had entirely disappeared and the nerve was normal

Now, in this case I might have accepted the dictum of the gentleman who put the glasses on her, had it not been for two facts one was, that it was not a simple congestion and blurring of the disc, but a swelling from three quarters to one dioptric Her condition when I first saw her was such that it might be denominated "woolly disc" The second fact was, that on March 24, 1882, three years and a half before she had the typhoid fever, the same lady had been a patient of mine, and on turning to my record book I found this diagnosis "Nerve congestion, asthenopia, astigmatism against the rule R E, 0 50 Dc ax 90 deg L E, 0 50 Dc ax 60 deg" At that time the cloudiness about the optic nerve and the asthenopia disappeared after the glasses were adjusted I was therefore in a position to recognize in this case the difference between an apparent optic nerve congestion accompanying astigmatism, and a true neuritis which developed after typhoid fever Had the gentleman above referred to been aware of these facts he might have been more charitable in his remarks In this connection it may be of interest to note the fact that her brother had also neuritis following typhoid fever eleven years previously He was taken sick on June 6, 1874, at 17 years of age The fever continued eighty days The attack was very violent characterized by delirium, coma, etc when at its height The diagnostic symptoms were the regular rise and fall of temperature pain and tenderness in the right iliac region, rose spots, typical tongue and diarrhea with yellow ocher stools When convalescing, had trouble with his eyes, which were examined by Dr Howell Thomas an oculist of Richmond, who stated he found neuritis, shown by "woolly discs" This report I received from Dr John N Upshur, a prominent physician of Richmond who attended both cases, and from this report I should not consider he has confounded meningitis with typhoid fever

Case 2—R H S , age 28, of Clifton Forge, Va , was sent to me by his physician on April 24, 1893, for treatment of his eyes which had become defective during an attack of typhoid fever, commencing July 4, 1892, and from which he did not fully recover until October, 1892, nearly four months His sight continued to grow worse in spite of his steady improvement in general health When I first saw him, both optic nerves showed decided atrophy of the discs His vision was right 5 200, left ½ 200 I put him on strychnia sulp and dil phosphoric acid, grains two to the ounce He commenced with 10 drops of this mixture after meals, and increased one drop each dose without showing any toxic symptoms until he was taking 52 drops, or one fifth of a grain of sulphate of strychnia at a dose On May 4 vision was, right, 12-200, left 5-200 , May 10, right 14-200, left 12-200 , May 13, right 16 200, left 14-200 , May 18, right 20 200, left 17-200, which indicated a steady improvement, as the right eye had four times as much vision and the left thirty-four times as much as at the first examination three weeks previously The type was changed at each examination so that he could not bring his memory to aid his sight and give false results When he reached the dose of one-fifth of a grain three times daily he showed decided toxic symptoms, when it was reduced to one-seventh of a grain, and he still continues the treatment

The case is interesting, both as one of white atrophy following typhoid fever (originating probably as neuritis or papillitis), and as a case of atrophy that made steady improvement under treatment, although he had been nearly blind several months

Case 3—Nellie Kilmartin, age three and a half years, was sent to me October 11 by Dr John Herbert Claiborne, Petersburg, Va She was perfectly blind in both eyes, could not distinguish a bright electric light in a dark room The right optic nerve was slightly blurred in outline and decidedly pale , the left gave a perfect picture of neuritis descendens She had been sick two or three weeks with fever closely resembling remittent, supposed to be of malarial origin She was given 2 to 3 grains of quinin daily for three or four days until she had taken 40 grains in all She complained of some headache and said her eyes hurt her, but had no signs of meningitis I put her on iodid of potash in gradually increasing doses until she showed its physiological effects and then added strychnia and dil phosphoric acid to the treatment She was brought to me regularly about once a week until the end of December After the first week she began to see light and from that time steadily improved I saw her the latter part of February, 1893 and her sight was perfectly restored, both optic nerves being normal

This case of neuritis I attributed to malarial poisoning, as I thought the others due to the pathological alterations attendant upon typhoid fever, on the grounds above given I have no comments to make and simply submit them for discussion

Note —Dr Oliver has since written referring me to his articles in Vol IV of Keating's Cyclopedia, and Vol II of Burnett's System of Diseases of the Ear, Throat and Nose, for his views on this subject

Dr de Schweinitz—When I wrote to Dr White concerning his experience with optic nerve atropy in fever I was under the impression that he wished data only in so far as typhoid fever was concerned I was not aware that the Doctor intended to cover a more extensive ground , otherwise I might have added other cases to those which I had reported I indorse thoroughly Dr White's use of strychnia in optic nerve atrophy, especially its use in full physiological doses, believing that by these alone good results are produced, while practically no effect is achieved by the ordinary doses which are administered In discussing blindness after fevers it was very essential to eliminate the possible influence of quinin, which I have no doubt Dr White has done in his case, and which, indeed, was practi[illegible] excluded by the exceeding smallness of the dose Nevertheless, small doses of quinin in patients exhibiting idiosyncrasies are quite capable of producing blindness I have seen temporary amaurosis follow the administration of 15 grains of quinin in divided doses during twenty-four hours, and Dr Horatio Wood of Philadelphia, has reported a like result after the exhibition of 12 grains

Dr White—Dr de Schweinitz seems to think that there was a possibility of this case being blind from the use of quinin, a thing which I carefully considered before attributing the blindness to optic nerve trouble caused by the fever I have never seen as little as 2 grains of quinin at a dose produce blindness Two or three grains daily until she had taken 10 grains would hardly have been sufficient to produce an effect like this I have seen cases where blindness was apparently produced by malarial influence before quinin was given These cases usually recover

---

ECCENTRIC POSES OF THE HEAD

Read in the Section on Ophthalmology at the Forty fourth Annual Meeting of the American Medical Association

BY J ELLIOTT COLBURN, M D

PROFESSOR OF OPHTHALMOLOGY CHICAGO POLICLINIC

In the following paper I wish to call attention to a few cases illustrating a large class of malpositions and eccentric poses of the head, due to lack of equilibrium between the motor muscles of the eyes These malpositions are assumed by the patients, either to prevent diplopia in paralysis, or to relieve the strain put upon weak or illy balanced muscles Such cases are frequently referred to the orthopedic or general surgeon as wry-neck or spinal curvature, and in a case now under my care, an operation upon the neck muscles was seriously considered for the relief of an eccentric pose, due to insufficiency of the right exterior and superior recti

Case No 1—Patrick K , strong, well built, and despite his defective eyes, well educated, applied to me in July, 1887, for a correction which I found to = O C + 3 G S + 1 25 cyl ax 90 V = 20 30 He carried his head thrown back, mouth partially open and nostrils dilated, thus presenting a most ungainly and unprepossessing appearance In this, the habitual pose of the head, he had binocular vision and had experienced no inconvenience except that attributable to ametropia With head erect and in the normal position he suffered annoying diplopia, vertigo, and after a brief enforcement of this pose a severe headache with nausea The muscle test with prisms, head in normal position, gave a constant right cataphoria 15 degrees, exophoria 10 degrees There was no evidence of ptosis Repeated examinations giving about the same result, I made an advancement of the superior rectus of the right eye and a tenotomy of the opposing muscle Two months later we found that he carried his head in almost the normal position, and when reduced to the normal manifested 2 degrees of hyperphoria This was corrected by a tenotomy of the superior rectus of the right eye, leaving an exophoria = 2° with abduction = 10° = adduction = 20°

As the patient now maintained his head in the normal position and complained of no asthenopia, I advised him to return in a year, or sooner if he experienced annoyance Almost two years elapsed, however, before his return, and upon reexamination I found no exophoria, asthenopia or any symptoms that could be attributed to his eyes, both pose and movement of the head being normal

Still another case involves about the same muscle condition, but in addition to the pose of the head the patient was subject to epileptiform attacks, occurring one in two or three days History as follows

Case No 2—Mary R , age 15 years, strong, well developed, and in good health but r the fits to which she was subject

The patient rarely attempted to pose the head in a normal position, always complaining of vertigo when attempting to do so The only way in which it could be avoided was to throw the head far backward In this position she could see objects on the horizon line without other annoyance than that due to the position of the head When the head was firmly held in the normal position, and the eyes were directed to the horizon line, there was found to be right-hypo exophoria, i e the right eye was directed down and outward Under atropin vision = 20 80, which was corrected by + 1 D In order to correct the muscle error, the right superior rectus was advanced and a guarded tenotomy made upon the inferior rectus Later, the right externus was cut and the internus advanced In about two months after the first operation the head could be carried constantly in the normal position, and the eyes soon gained the normal freedom of movement There still remained a tendency outward of 3 degrees which was not corrected About a year later, and following the first menstruation the epileptiform attacks ceased

Another type of malposition sometimes obtains in patients afflicted with esophoria or exophoria A case evincing this occurred in a lad of 14, in good general health, and who presented no nervous or other symptoms of disease, the left side of the face, however, was illy developed He habitually inclined his head to the right with a disposition to open the mouth unsymmetrically, the left angle being more obtuse The eyes were directed strongly to the left, in this position vision was 20 20 and binocular The head placed in the normal pose gave an exophoria = 15° to = 20°, adduction =0, abduction =25° test with prisms in appropriate position The image was inconstant

I made double tenotomies of the externi and advanced the internal rectus of the left eye Five days after the operation the exophoria = 5° remained constant and two months later I again tenotomized the left external rectus obtaining 1 degree of esophoria The patient was discharged with directions to return in three months at least, and sooner if further annoyance was experienced Subsequent examination, head held in normal position, gave no evidence of heterophoria

Still another form of malposition gives its unfortunate possessor a decidedly repulsive aspect The head is bent forward, the chin is markedly retracted and the features often mold themselves into an uncanny grimace These patients have binocular vision with the head in the above described position, but directly the head is adjusted to the normal pose a heterophoria is manifested Young patients frequently struggle violently to resume the malposition

Case No 3—G K, age 17 years, maintained his head in this distressing posture, displayed an awkward staggering gait, nervous and illy coordinated movements of the head and body V =20 60, hyperopia = + 2 50 D O S hyperphoria = 3 degrees esophoria = 10 degrees (adduction 40 degrees abduction 0 degrees) He was given a full correction There was no improvement in position or coordination, therefore I concluded to correct the left hyperopia This was done by graduated tenotomy and advancement respectively of the superior and inferior recti in the right eye Two weeks later as there still remained 10 degrees of esophoria I made a double guarded tenotomy of both internal recti resulting in an esphoria of 1 degree

Much difficulty was experienced in compelling patient to maintain the normal pose of the head, but in an exceedingly brief space of time his gait appearance and manner of speech were much improved Four months later as some esophoria still persisted, I again tenotomized and fully corrected the error This patient was particularly unfortunate in his infirmity, as from early childhood he had been exceedingly sensitive regarding his appearance, and greatly mortified that even under the instruction of the best masters, he had been unable to amend for any appreciable length of time his noticeably eccentric attitude The correction operations effected such a surprising transformation, that after an absence of some months from his family they were enabled to recognize him only by his voice I have never seen so complete a metamorphosis in one's appearance as he underwent I regret that I am not allowed to present photographs In order to give an idea of the full extent of the affliction, these patients must be seen while moving about and not aware that they are observed

In these cases there may never be a history of strabismus, the patient from early childhood adjusts the head to the position best calculated to avoid diplopia, and frequently there is no history of asthenopia or any symptom that could be classed as neurasthenic

Still another modification of this form may obtain where it is not a question of double vision, but of muscle deviation involving both superior recti and not uncommonly the levator palpebrarum, and more or less stenosis of the aperture Such cases demand tenotomy of the inferior and advancement of the superior recti and levator palpebrarum, and a free canthoplasty to correct the malposition Canthoplasty, advancement of the levator palpebrarum, tenotomy and advancement of recti muscles all can be accomplished in the above mentioned routine at a sitting, still I consider a more preferable method includes the canthoplasty and advancement of the levator in a first operation, and some weeks later, the operation upon the ocular muscles proper, as the correction of the ptosis and aperture may, in a degree, modify the operation for the recti muscles

These are typical cases and subject to many modifications, in none of them did I find a history of nervous disturbance occurring at any time The only symptoms simulating the latter condition were the tendency to incoordination, grimacing and awkward posing of the body It requires great patience, some tact and a thorough study of the conditions governing these cases to properly correct such errors From these causes of malposition must be eliminated maladjustments of the neck muscles, deformities of, and injuries of the head

A Case of Malposition following an unguarded complete tenotomy—Chas T, 15 years of age had been operated on for strabismus four years previously, and judging from my knowledge of the operator's work, there had been performed a complete unguarded tenotomy and no examination made to correct an existing hyperopia The left eye was directed out with slight tendency downward, the right followed, and binocular vision was secured by posing the head backward and to the right The movement of the left eye was limited toward the nasal side allowing but two milliamperes, from median line in that direction When the head was forced into the normal position the right eye was five milliamperes above its fellow An examination of the cicatrix showed broad and extensive adhesions After staining with India ink the sclero corneal junction to mark the normal position of the muscle, I made an incision and found the muscle attached below the equator of the eye and quite far back Advancing and raising the muscle to its normal position, I secured it by a double armed suture After recovery from the operation the patient was ordered to use his full correction under atropia and to return in six weeks Upon his return 4 degrees exophoria persisted, we tenotomized the external rectus, this fully corrected the error and head and eyes resumed their normal position These cases are not so infrequent following the old operation for strabimus

Malposition due to partial paralysis of the recti mus-

cles allowing the eye to move only to the median line and fixed for a definite distance —This form of anomaly is one of the most annoying with which we have to deal There is no position in which the head can be placed to secure uncomplicated proximal vision This is especially distressing if the patient be so unfortunate as to be unable to suppress the image of error

Case No 4—Mrs H , age 23 had homonymous strabismus with fusion at 2 mm pose of the head to the left or right, head in normal position at 20 feet, esophoria = 15°, adduction = 40, abduction = 0°, movement of the eyes limited to median line, left eye no power of abduction, vision 20 30, under atropin + 75 O D and O S gave 20 20

At the request of our patient we tried everything adapted to correct such errors, galvanism faradism massage, stretching, etc , of the externi muscle, in the endeavor to tone and stimulate the interni preparatory to tenotomy and advancement Three months of unremitting effort secured an abduction of + 30, a guarded tenotomy and advancement gave adduction 30° abduction 2° with normal position of the head and freedom from a constant vision of the nose Abduction continued below normal, but for central and proximal vision there was no annoyance In this case I advanced the external rectus of the left eye and made two tenotomies on each of the internal recti at different times before I secured central remote fusion

This patient has lately called upon me again, complaining of severe pain in the right eye, following every attempt to move the eye even to the median line Muscle tests showed that there was an eso phoria, or tendency of the visual lines inward equal to 8 degrees, but the total displacement inward (Landolt perimeter test) was, right eye fixing, left eye tended in 12 degrees, showing a tendency to pose the head slightly to the right in attempting to look at objects either at a proximal or remote point As the patient would not adjust herself to the abnormal relation existing between the eyes, and I could not persuade her to wear prisms, I corrected by making a guarded tenotomy upon the right internus, resulting ten days later in a remote and proximal fixation in the normal position without painful effort I presume it may be best, somewhat later, to correct the displacement in the left eye, making a guarded tenotomy, however, this I should not suggest to the patient unless she complains of further pain

The method which I adopt in all cases of asthenopia has been strictly followed in the management of these cases I first attend to the correction of errors of refraction, then after a sufficient time has elapsed the correction of the muscle condition is carefully considered I prefer the Stevens phorometer for low degrees of heterophoria, using the Maddox rod, and divide prism, etc , as aids in measuring the error and educating the muscles As to the technique of operations for tenotomy and advancement, I have but little to offer that is new, and nothing purely original

In the guarded tenotomy which I now make for the relief of very low degrees of heterophoria, I follow the plan suggested by Dr Stevens or Noyes, also Stevens advancement in errors of low degree, with the exception that I use a broader divulser to separate more thoroughly the numerous bands of attachment between the tendon and the ocular walls, as this latter condition may prevent the lengthening of the muscle and render imperative the tenotomy To attain the maximum effect of a complete tenotomy without danger of displacing the tendon, and to regulate the position of the future attachment I proceed as follows

Enter the conjunctiva just above the lower border of the muscle to be receded, separate the capsule and tendon from the conjunctiva, grasp the center of the tendon with the forceps and proceed as in graduated tenotomy, grasp the center of the cut tendon with broad fixation forceps and introduce the needles of a double armed suture, draw them through, transfix the conjunctiva as far back as you wish to displace the tendon, then bring them out through the conjunctiva, now complete the tenotomy, again using the divulser to separate the tendon from ocular walls, the suture is now drawn up and tied, but not too tightly Should the conjunctiva wound gape, close it with a light suture This operation secures both maximum effect and proper attachment

I have found it necessary, preliminary to operating for heterophoria, to make a thorough study of both pose and movements of the patient before measuring the muscle error or in any way embarrassing them The best plan is to draw their attention to books, curios, people, to distant buildings meanwhile observing closely and making notes of all interesting deductions, remembering the general rule that, "the head moves in the opposite direction to the projection of the visual lines " A careful chart should be prepared and notes made of every operation and its results, for usually several cuttings must be made before a perfect orthophoric condition in the normal pose can be obtained I have found it expedient to apprise my patients of this before commencing the operations As we are able to do all of the surgical work under cocain anesthesia, much of the terror and all of the danger of tenotomy has been removed

DR GOULD—I have had two or three cases that somewhat resembled those reported by Dr Colburn One patient carried his head back in order to avoid double vision due to heterophoria By carefully adjusting glasses, his muscles were strengthened so that he held his head in a normal position One other patient had quite a distortion of his features, his forehead being wrinkled in concentric curves clear from his eye to the roots of his hair It was very noticeable After three months he was holding his head straight with the skin of his forehead nearly straightened out I had still another case somewhat similar to this one

DR JACKSON—I that that the class of cases to which Dr Colburn has called attention is a very important one, and one to which the attention of the profession needs to be more generally directed I feel like taking exception, however, to his classing them as cases of heterophoria, if I heard some of them correctly They are rather cases of paralytic squint in which it is impossible to obtain binocular vision in the central portion of the field of vision I have seen quite a number of these cases, and have also seen the other cases, which could be classed as heterophoria because binocular vision could be obtained in all portions of the field of vision though only with undue effort When Dr Stevens gave us the new terms, the "phorias," I hoped that they would be applied only to cases of muscular error which correspond to concomitant squint, and that for these cases of special weakness in one muscle or group of muscles we might still use the very significant term, insufficiencies

---

WHEN THE MERCURY WENT DOWN —The *Chemist and Druggist* offers us the following Mrs Mulcahey "Shure, doc-ther and is it thrue that little Jimmy O'Toole bit yoore termomety in two and swallowed the mercury?" Doctor Yes, my dear madam, it is, and the boy is dead " Mrs M "Shure docther, an' it were a cold day for Jimmy, poor bye, whin the mercury wint down " Doctor "Yes, madam, he died *by degrees* "

TWO MORE CASES OF ORBITAL AND OCULAR GROWTHS, WITH SUBSEQUENT HISTORY OF CASES PRESENTED LAST YEAR

Read in the Section on Ophthalmology at the Forty fourth Annual Meeting of the American Medical Association

BY JOSEPH A WHITE, A M , M D
RICHMOND VA

I here present for your consideration two cases of ocular growths which have come under my observation since our last meeting, thinking they might be of interest

Case 1 Orbital Growth, Fibro sarcoma (Post-ocular) —Betty Lytle, colored, age 24 of Blackstone, Va , came to me Sept 27, 1892 In May, 1892, she had consulted her physician, Dr Harris, about a severe pain across the forehead and through both temples He could find nothing abnormal about the eyes, except a slight redness of the conjunctiva of the left eye He treated her for neuralgia, but the pain still persisted and gradually grew worse He could get no history of syphilis, but thinking the pain might be due to a gumma he put her on iodid of potash, but with no relief The left eye soon began to show prominence without local signs of inflammation He then concluded to send her to an oculist and gave her a letter to me On the way she stopped with friends in Petersburg who advised her to consult a physician there He advised her to have the eye punctured and the fluid drawn off as he expressed it She returned to Dr Harris with this advice, which he did not follow, as he could find no signs of a collection of fluid He then sent her to me again I found the eye very prominent, so much so that the lids could hardly be closed, although she could still see fairly well I attempted to remove the orbital growth and save the eye, but it was so large this was not practicable and I removed eye and tumor, which nearly filled the orbit

I have had a letter from Dr Harris the past month saying she was annoyed at times, especially at night, with pain in the orbit, but he could find no signs of recurrence The woman looked well and was doing her usual work I sent the growth to Dr William M Gray of the Army Medical Museum, who promised me a full report on its nature, as well as a section of the growth for this meeting, but have not received it He stated, however, that it was a fibro sarcoma of the orbit

Case 2 Melanotic Sarcoma of Choroid —Miss F , of Milton, N C , a lady of about forty years of age was sent to me Feb 22, 1893 by Dr Dodson her physician, to have her left eye enucleated, because it was blind, disfigured by a large black spot and was giving her constant pain I found the eye to be totally disorganized, anterior chamber obliterated, lens cataractous and a large black patch of the sclerotic about a half inch long and a quarter inch wide above and to the outer side of the cornea I diagnosed melanoma of the eye and feared it had already penetrated the sclera posteriorly As the tension was not increased at all and the eye was less painful than it had been it was enucleated Feb 23, 1893, under cocain The optic nerve was drawn out and cut as far back as possible As far as a microscopic observation went, the growth had not penetrated the sclerotic, which was seemingly intact

I sent the eye to Dr Gray who reported it to be a melanotic sarcoma originating in the ciliary bodies or choroid, that it was of a mixed variety, composed of large and small, round and spindle cells, that it had infiltrated through the sclerotic, forming small pigmented nodes on its outer surface He sent slides of this tumor, which you can examine These two cases will each probably have recurrence of the growth, although it is not certain

Last year I presented four cases of orbital and ocular growths operated on at the clinic of the Richmond Eye, Ear, Throat and Nose Infirmary, within four months—two by Dr Dunn and two by myself I also exhibited very handsome micro photographs of these growths which were most abominably reproduced in the JOURNAL, giving no idea of the original plates Two of these were so-called malignant fibroids of the orbit (Cases 2 and 3) One (Case 1) was a melanotic sarcoma of the choroid, similar to the one I have just presented The fourth one was an orbital sarcoma of the choroid which Dr Gray called a tuberculous growth, because of the peculiar microscopic appearances resembling tubercle more than anything else Thinking the further history of them might be of some interest, I have taken the liberty of appending it to the above report Case 1 (melanotic sarcoma of the choroid), has had no recurrence in the orbit I wrote recently inquiring about his condition and was informed that he was ill with some obscure liver trouble, but that his eye was pretty much as when I saw him last From this information I concluded he was suffering from a metastatic malignant growth of the liver

About eighteen years ago I had a similar experience I enucleated a large growth of the orbit (the eye had been previously removed) which on examination proved to be a melanotic sarcoma It was half as big as my fist and projected considerably beyond the orbit It was so firmly attached to the orbital walls that I had great difficulty in freeing it from its attachments, and was compelled to remove almost entirely the superior orbital plate I applied Vienna paste to the remainder of the orbit, and the man made a rapid recovery I expected a speedy recurrence, but during the three years he lived there was no return of the growth A postmortem, however, showed that his death was due to a malignant growth of the liver, exemplifying the metastatic nature of these growths

Further history of the case of malignant fibroid of the orbit (Case 2 reported last year) Patient reappeared at the clinic July 25, 1893 Tumor had grown again It had chosen as points of origin all the areas of the bone from which the periostdum had been stripped in the former endeavor to eradicate the growth This was found out during the operation for the removal of the growth The bleeding was excessive The tumor was found to have passed backwards into the sphenoid fossa and had sent its prolongations through the ethmoid plate Negro returned to the clinic only two or three times to have the wound dressed Reappeared Dec 5, 1893 Tumor was quiet for three months, when it began to grow again It now became a huge fungus which protruded from the orbit, infiltrating the adjacent skin Attempt was made to clean out the orbit as far as possible, but operation was unsatisfactory and bleeding was excessive Operation did not check the growth of the tumor, which had gone into the antrum, nasal cavities, etc Patient died of exhaustion in February when the tumor had attained a size almost beyond belief

Further history of case of tuberculosis of orbit (Case 4 reported last year) Appearance of a growth between the eye and the upper part of the orbit in the autumn of 1892 As it gave the patient little inconvenience no operation was done until March, 1893, when attempt was again made to remove the tumor without enucleation of the eye Operation apparently successful No return up to May 21, 1893 Microscopic examination of tumor removed showed it to be a small celled sarcoma which had infiltrated the lachrymal gland Tumor will probably return This second examination was made by another pathologist who did not find the peculiar tuberculous appearances, "the nests," described by Dr Gray when he examined the growth Case 3 was one of fibroma of the orbit and I expected it to recur and speedily, too, because fibromas of the orbit while not regarded as malignant in structure, are practically so from their tendency to recurrence and because, apparently, I had not succeeded in totally enucleating the growth, but rather to have amputated it at the sphenoidal fissure through which it seemed to pass Up to one month ago, however, nearly eighteen months after the operation she has shown no signs of recurrence What the future may develop I can not say, but trust I may be mistaken in my unfavorable prognosis

NOTES ON BIFOCAL SPECTACLES IN APHAKIA

Read in the Section on Ophthalmology, at the Forty fourth Annual Meeting of the American Medical Association

BY H V WURDEMANN, M D
MILWAUKEE, WIS

The satisfaction expressed with bifocal glasses by hyperopes, whose presbyopia necessitated stronger convex lenses for reading, led me about a year and a half ago to advise this form of spectacles for aphakic patients The conclusion reached seemed so natural to my mind that I believed, until I examined the literature of the subject, that the same idea must have occurred to many of my colleagues, and that such glasses must have been used for cataract patients, practically since the introduction of the cement bifocal Due and strict search having been made nothing was found in the literature, and but little new was gathered from the manufacturing opticians concerning the trial of such glasses by other ophthalmists

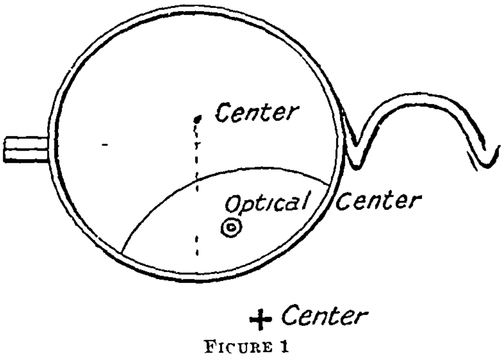

Figure 1

The most appropriate form seems to be that in which the refractive value is made greater by cementing a semilunar shell to the lower part of the larger lens On account of the thickness of the strong convex lens (from 8D to 12D) the "split or Franklin bifocal" is not applicable The cost of grinding the reading on top of the distance lens militates against the combination being made in one piece The cement bifocal is comparatively cheap and has given satisfaction It has been found advantageous to modify the ordinary form by making the spectacle eye of a high oval, nearly round, as this gives a larger field for distant vision, also to make the reading shell small and placed diagonally a little to the nasal side, as was advocated some years ago by Klein in his form of bifocal lens (See Fig 1) This gives a better field for near vision and likewise diminishes the prismatic effect of the larger lens There is an average difference between the visual lines for the near and far distance of 2 mm , which amount of decentering in a 10 D lens would make an effect equal to Pr 1 25 D, an amount of artificial exophoria which may prove troublesome. In some instances I have found it advantageous to decenter the larger lenses upwards 1 to 2 mm , varying with the case, as the unpleasant upward projection of the ground is thereby relieved It is advisable to place the strongest convex surface away from the eye in all instances, and to grind the cylinder on the posterior aspect of the glass, as has been advocated by Gould

When the formula is for simple convex lenses only, the lens may be made concavo convex, and the reading shell is best cemented on the posterior surface of the larger lens, but when a cylinder is involved on account of the difficulty in grinding it on so thin a shell, it must be placed in front In compound formulas the periscopic form is out of the question and the cylinder should be ground on the plane side of a plano-convex lens Nearly all eyes, aphakic ex operatione, are sufficiently astigmatic to warrant the cylindrical correction, and thus it is but rarely that we may give our patients the periscopic form of lens

The advantages of bifocals in aphakia are those which presby-hyperopic patients acquire by the use of one pair of glasses for all vision They may be properly given to nine out of ten cataract patients whose resulting vision after operation allows them to read ordinary print with their correction

805 Grand Avenue

Dr Murrell—I have been using bifocal lenses after cataract extraction for a number of years I have several patients wearing them now My next door neighbor has worn a pair for several years, has good vision and can read fine print all day long I advise the use of them

Dr Ziegler—I have been ordering these bifocal cataract lenses for several years, in fact ever since bifocals came into general use They are undoubtedly the most convenient lens for aphakic eyes Even where only one eye has been operated upon, bifocals are superior to the more clumsy 'reversibles" I think Dr Wurdemann has overlooked the very important "toric" or "ellipse" lens, which was presented before the American Ophthalmological Society by Dr Harlan in 1885, and subsequently discussed in a paper by Dr Green This is especially advantageous where we have a cylinder in combination with very high sphericals It is composed of two cylinders ground on the same side of the lens, and at right angles to each other As one cylinder is stronger than the other we secure the effect of a sphero cylinder, the balance of the spherical is then ground on the other lenticular surface We thus practically divide the spherical on each surface of the lens, and then grind the cylinder on one of these spherical surfaces This makes a much thinner lens than the old form where the cylinder alone is on one side and the large spherical bulge is on the other But aside from being a thin lens, its chief advantage lies in the fact that it furnishes a greater clearness of visual field, which will be promptly appreciated by the patient This lens may also be ground periscopic. The bifocal slip can easily be added to either form

Where the two eyes have been operated upon, I have sometimes prescribed a distance correction for one eye, and a reading correction for the other This arrangement is particularly applicable in those cases where there is considerable muscular insufficiency It allows one eye to enjoy clear vision for distance, and the other clear vision for reading I ordered such an adjustment recently for a physician whose left eye I had operated upon for zonular cataract, while the right one still retained good peripheral reading vision As there was considerable muscular deviation in the vertical, a prism was added to the glass He was ordered H O D S — 2D for reading, O S S — 9 D P ⊃ 4° base down, for distance

It may be well to bear in mind the fact, that discomfort from the use of cataract lenses may be entirely due to muscular deviations, and we should order the proper prismatic correction wherever needed

---

PERNICIOUS HYPERTROPHIC CONJUNCTIVITIS AND ITS TREATMENT

Read in the Section of Ophthalmology at the Forty fourth Annual Meeting of the American Medical Association

BY CORNELIUS WILLIAMS, M D

ST PAUL MINN

I shall not occupy the time of this section by a definition of the pathology of this affection Under the generic name of trachoma, the disease is well known to all of you Since, however, a name should be definitive of as many pathological features of an affection as may well be, to my mind the name which I have chosen is more appropriate than any that I have seen applied to this morbid condition

Pernicious hypertrophic conjunctivitis, as usually presenting itself to the surgeon, is chronic and complicated The disease will have involved the cornea and there may be, or have been iritic implication, as even the deeper tissues of the eye do not escape In a case which I had an opportunity of intimately observing, I was able to fix the time of incubation at five days from the time of inoculation to the time of declaration of the disease, though I can well understand that the term may vary The emphasis of the primary declaration, I fancy, will depend very much more upon the quality of the seed implanted in that particular case, than upon any peculiarity of the culture medium I have seen cases in which the entire conjunctiva had increased more than twenty-fold in thickness, in as many days, and others in which the hypertrophy was not considerable, even though the disease had existed many months

The invasion of the cornea does not always take place through an abrasion of the epithelium, but may, I believe, be accomplished through the lymph channels When once the cornea becomes affected, the ciliary spasm brings a largely increased blood supply to the conjunctiva, and the vicious circle is established The later phases of the disease are of great interest The form of degeneration marked by the development of trachoma bodies may be absent entirely in some cases and abundantly present in others Those cases that have been the subjects of irregular and severe treatment of different kinds are rather more apt to present that peculiar manifestation, conjoined with atrophic spots, while such as have not been treated at all, save by simply cleansing, although long in existence are on the whole better off than those in which the treatment has been harsh

That the disease, as we now find it, ever originates in any other way than by direct contagion, I think few will maintain That there are a great number who, in all probability, receive the contagium on the conjunctival surface, and escape the development of the disease, is due to the fact that an actual lesion of continuity is necessary to infection I have seen cases that make me believe that pernicious hypertrophic endo rhinitis may result from the conjunctival affection, by auto-inoculation In the case of a Russian girl of 6, the turbinated bones had undergone complete atrophy from this cause It is the exceptional case in which an eye is lost through this disease, though many are damaged beyond repair

The disease is very frequently confined to one eye, or may affect the second eye only in a limited degree It is not unusual to see a virulent type of this inflammation in one eye, while the other member presents the appearance of slight hypertrophic changes, but little secretion with absence of corneal invasion With appropriate excitation, however, the morbid process in the seemingly favored eye will kindle and attain a dangerous exaltation, all within a very few days Once this pernicious hypertrophy has actively involved the entire conjunctiva, it never again recedes to its former line of behavior

This affection may last an average lifetime It is curable, but at an expense of a certain loss of the conjunctival substance, the degree of loss in direct proportion to the hypertrophy It goes without saying that in addition to the tissue loss, as the result of the disease, injury inflicted by way of treatment is responsible for much of the deformity of the tarsal envelopes, and consequent damage to the eye so frequently seen

Treatment —There is no disease of the eye so often ill treated as pernicious conjunctivitis In the primary affection, ice should be used with much caution. While a valuable remedy, it may actually aggravate the affection by inducing a vasomotor paralysis of the conjunctival vessels Ice cloths should be thin —bits of absorbent cotton are better—and should not be used longer than an hour at a time, with an interval of an hour Mild astringents should be used from the very first Nitrate of silver, 1–5000, or bichlorid of mercury, 1–20000 or 40000, the conjunctival sac should be very gently and thoroughly flooded with one of these solutions, alternating with a warm solution of boric acid, ten or twelve times a day, or oftener, how often must be left to the discretion of the surgeon Of one thing, however, he can be assured, i e, in very many, if not in all cases, any application followed by reaction apparent to the eye of the surgeon, will be resented by the eye of the patient This reaction is the surgeon's guide He may use the astringent applications as strong and as often as the eye will bear, without apparent reaction If he transgress this rule he will lose ground I have used the bichlorid solution 1–400, with only a little smarting and increase of redness, lasting for five minutes, while on the other hand, a 1–3000 solution, is sometimes highly irritating An application which causes pain for longer than five minutes, while it may do good is almost sure to do harm This, I believe to hold good for any stage of the disease but it is, of course, less true in the later stages It may be well to bear in mind that the condition of great hypertrophy is a condition of great tolerance and insensibility which, however, may only last a few days after active treatment begins

The hypertrophy will begin to diminish, and does diminish, *pari passu*, with the diminution of the secretion The retrograde metamorphosis is marked by lessened secretion Whatever the treatment adopted, I have never observed lessening of the hypertrophy until the secretion had very much diminished I am convinced that, in any stage of the disease, the frequent application in the course of the day of a solution of sulphate of copper or the mercury bichlorid 1–30000 or 1–50000, will accomplish more than can be attained by a single application of either remedy of sufficient strength to produce visible reaction In fact, that the successful treatment of pernicious conjunctivitis, whatever the agent employed, must depend upon the frequent use of that agent, and in such strength only, that no apparent reaction shall occur When trachoma bodies appear, the application of jequirity, or better, the expression process, certainly much hastens the matter of involution, but it is questionable if the conjunctival surface will have been left in so good a condition after either jequirity or expression, as it would have been had the method of very frequent treatment with the bichlorid, or some similar acting drug, been adopted Now, as to the choice of the medicament, I think mercury bichlorid perhaps the best, but I doubt not that there are many substances which might be successfully used instead, just as in urethritis, which this disease so much resembles, there are many remedies Many surgeons are agreed that the most proper way of treating the urethral disease is by means of mild and frequent medication

It would seem like a work of supererogation, to thus dwell upon the minutiæ of treatment before this section, but my personal experience, costly enough has taught me that able surgeons in high places do not always address themselves with that conscience to the treatment of this affection that its importance demands, and which the patient has a right to expect from his physician Atropin is absolutely indispensable as an adjunct in the treatment of pernicious conjunctivitis It should be used early, even before any implication of the cornea has declared itself, for by allaying ciliary spasm the first part of the process of the vicious circle establishment is rendered impossible It ought to be incredible that the imperative indication for the use of a mydriatic could be overlooked by the surgeon in the treatment of the disease in question, yet I, myself, am the possessor of a ruined eye, and due to this very oversight on the part of a surgeon generally as competent as any in the country

The detail of the toilet of the eye, after whatever application, is of importance In treating the eye, instead of a camel's hair pencil or a dropper, I use a small probe, so wound about the end with absorbent cotton that an expanded portion projects This is dipped in the solution to be used and the turned lid is flooded with the solution which readily flows from it The lower cul de-sac is similarly treated, after which the ciliary margins are gently freed from every adhering bit of secretion and then carefully dried If this is not done the edges of the lids are constantly itching and it requires unusual control on the part of the patient to avoid rubbing the eye, and consequent aggravation of the disease process

When I first saw pernicious conjunctival disease treated, it was done entirely with sulphate of copper in solid form, and I speak of that method of treatment here to condemn it as brutal, painful, unskillful and unsuccessful I have seen children with hypertrophic conjunctiva, with and without trachoma, actually become men and women, the while constantly treated with blue stone, and after seven years they were no better than at the beginning Surely this is an opprobrium and should suffice to damn that method of treating the disease I wish particularly to condemn any irritating application, and especially peroxid of hydrogen, in the acute corneal ulcers of pernicious conjunctivitis I well remember the pain which the peroxid produced in my own eye, and from the use of which started an iritis that, untreated, resulted in complete closure of the pupil with its inevitable consequences, and it is only by such malpractice that an eye can be lost in this affection

It is needless to say that abstinence from use of the eyes is of prime importance The disease, difficult enough to cure at best, is aggravated by every considerable effort of accommodation and convergence

CORRESPONDENCE

Diphtheria at St Paul

Minnesota State Board of Health and Vital Statistics
Offices of the Secretary and Executive Officer,
Red Wing, Oct 19, 1893

To the Editor —The following is the reply of the Commissioner of Health to your inquiry

"In reply, I would state that there was very little in connection with the whole matter A number of families having children at the Neill School wished to get them transferred to other schools—the Neill School, as I understand it, being rather overcrowded, and to get a good excuse for so doing, got up this diphtheria scare The records show three cases of diphtheria as having occurred within the radius of the Neill School within a period of nearly a month, which is very much unlike the statements made by the people in that vicinity, both publicly and privately I refused to close the school, but Supt Gilbert, under the pressure that was brought to bear upon him by these people, ordered the school to be closed over Friday, Saturday and Sunday, if I remember right, on his own responsibility and during that time had it disinfected, etc That is all there was to it You know the value of newspaper reports, and I am glad you propose to verify by reference to headquarters of each State Yours C N Hewitt,
Secretary

Ethics Again—The Milk in the Cocoa Nut

Richmond, Va, Oct 21 1893

To the Editor —At the annual meeting of the Medical Society of this State, held at Charlotteville October 3, the resolution offered by Dr Upshur of Richmond, affirming our loyalty to the present code of ethics, was passed with only two dissenting votes—the move to "lay on the table" and his second, Dr Hunter McGuire, made a strong speech in favor of the resolution, affirming that the medical men in New York who desired to "let down the bars" were influenced solely by the selfish purpose of getting consultation fees from homeopaths, Very respectfully,
W W Parker

Blank applications for membership in the Association, at the Journal Office

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

SUBSCRIPTION PRICE, INCLUDING POSTAGE
PER ANNUM IN ADVANCE $5 00
SINGLE COPIES 10 CENTS

Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
NO 68 WABASH AVE CHICAGO ILLINOIS

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association All that is necessary is for the applicant to write to the Treasurer of the Association Dr Richard J Dunglison, Lock Box 1274, Philadelphia Pa, sending him a certificate or statement that he is in good standing in his own Society signed by the President and Secretary of said Society with five dollars for annual dues and subscription for THE JOURNAL Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J DUNGLISON, M D Lock Box 1274, Philadelphia Pa

SATURDAY, OCTOBER 28, 1893

TURKISH BATH IN MEDICINE

The Turkish bath as a therapeutic agent is coming into greater prominence every year, especially in asylums and sanitariums Private baths in cities are in many instances largely supported by patients sent from physicians In Europe many of the large hospitals and all the sanitariums are equipped with these baths, as essentials in the treatment of disease The thirtieth anniversary of the first public bath opened in this country, at Brooklyn, N Y, was celebrated last week by DR C H SHEPARD, the founder In an after-dinner address on this occasion, DR SHEPARD reviewed the early history of the baths in the Roman empire Three thousand years ago the Greeks used the hot water and hot air bath, which was the same as our Turkish baths Its use was originally a religious rite to prevent evil spirits from taking up their abode in the body In Roman civilization it attained a perfection that seems wonderful even to-day The largest bath ever constructed was by DIOCLETIAN, and could accommodate eighteen thousand bathers at one time and was over a mile in circumference The Pantheon of Rome, now used as a church, was built as a vestibule to the baths of AGRIPPA At one time there were nine hundred baths in Rome, and every person was obliged by custom and law to use them every week or oftener At Alexandria in the seventh century, the number of baths reached over four thousand It is a curious fact only recently recognized, that during these ages when the baths were so common and popular, no epidemic diseases prevailed Rome, Alexandria and Constantinople, and also the earlier Grecian cities, were singularly free from plagues and contagious diseases during these times As soon as these nations were overrun by barbarians, baths were abandoned, and plagues and epidemic diseases began These baths were lost to civilization, except in a small way at Constantinople, until 1840, when the first bath was opened in England It is said, however, that the bath at Buda Pest has remained in operation from the date of its original construction by the Romans Now there are about five hundred baths in Great Britain and about one hundred in this country Starting at first as luxuries, they have grown to be therapeutic measures of great and increasing value In this address DR SHEPARD reviewed the opinions of eminent physicians in Europe, of the nature and value of the bath, pointed out the possibilities of its influence on disease in the future, and concluded that no present remedial measures gave greater promise in the treatment of disease

In this day of anniversaries it is pleasant to note this event, and to realize that the bath, which has occupied so prominent a place in the highest civilizations of the world and which is so closely allied to sanitary science, is coming into prominence again. To DR SHEPARD the founder (and member of our ASSOCIATION), is due great credit for establishing the first bath, and so persistently urging its merits and claims on the medical public

THE FIRST POSTMORTEM RECORDED IN THIS COUNTRY

The centennial of the Connecticut Medical Society last year, was marked by several historical addresses concerning medical matters a century ago Old papers and records, physicians' account books and diaries, and old letters and legends, were all examined, and many very interesting stories have been gleaned from them One of these old records, dated March 11, 1662, makes note of a vote in the General Court of Connecticut, granting unto MR ROSSITER twenty pounds for opening the belly of KELLEY'S child, and his pains to visit the deputy governor, MAJOR MASON, and MR TALCOT, and other ministrations It appears from the long and minutely written account, that JOHN KELLEY of Hartford, had a daughter eight years old, who was taken ill of some form of bronchial pneumonia attended with delirium March 23, 1661, and died five days later During this illness she complained that GOODY AYRES, who was a general neighborhood nurse, was choking her, and kneeling on her belly, also pinching her She urged that her father should chop off the head of this nurse who was not called to take care of her. After short periods of sleep she would start up and cry out against this woman This delirium of persecution continued until death, in which she constantly asserted that GOODY AYRES was the cause of all her pains and torments The case was considered so unnatural and untimely that a jury of six persons were called to make an inquest

GOODY AYRES was requested to come up and handle the body in the presence of others Among other signs was a reddish spot on the cheek nearest to Goody Ayres, and certain purging from the mouth, with stiffness of the arms, and black spots over the body, were regarded as suspicious Accordingly Mr Rossiter, who lived in Guilford twenty miles away, was sent for to examine the body Several days later he arrived, and with the assistance of the school master, William Pitkin, made the necropsy The following is the record made in the handwriting of Mr Rossiter He condensed his account into six particulars which he said in his judgment were preternatural

1 The whole body, the muscular parts, nerves and joints were all pliable, without any stiffness or contraction, the gullet only excepted Experience of dead bodies renders such symptoms unusual

2 From the costal ribs to the bottom of the belly in the whole latitude of the womb, both the scarf skin and the whole skin with the enveloping or covering flesh had a deep blue tincture, when the inward part thereof was fresh, and the bowels under it in true order, without any discoverable pecaney to cause such an effort or symptom

3 No quantity or appearance of blood was in either venter or cavity as belly or breast, but in the throat only at the very swallow where was a large quantity as that part could well contain, both fresh and fluid no way congealed or clodded as it comes from a vein opened, that I stroked it out with my finger as water

4 There was the appearance of pure fresh blood in the backside of the arm, affecting the skin as blood itself, without bruising or congealing

5 The bladder of gall was all broken and curded, without any tincture in the adjacent parts

6 The gullet or swallow was contracted like a hard fish bone that hardly a large pease could be forced through

This was signed by Dr Rossiter and was evidently intended to convey the idea of death from preternatural causes Mr Pitkin, the school master, followed with sundry observations on the symptoms of the case, and the incidents attending the death and body when laid out This was sworn to and attested by Mr Clark, Secretary of the colony Nothing further was done, and Goody Ayres moved away and the claim or suspicion of bewitching was forgotten In 1663 this same surgeon performed another autopsy on Rev Samuel Stone, who died suddenly The only thing mentioned was that this man had no gall bladder In 1659 a new disease appeared of "bladders in the windpipe" which seems to have been very fatal among children Some examinations revealed this state about this time A curious record of the examination of animals to find the cause of death, is noted in the records of New Haven as early as July, 1650 In a lawsuit over an ox, in which it was claimed that he was killed by overwork, one Edwin Parker examined the body and testified to its appearance The record states that the heart was full of blood, and the liver and lungs were swelled and the flesh was waterish

This Kelley case was the first necropsy that was recorded fully, and the surgeon, Rossiter, was probably the most eminent man of his time It is found from some old records that he received his education in England, and appeared in 1631 in the Massachusetts colony He was an intense loyalist and did not get along very well, but finally he came to Connecticut and lived and died much respected for his medical ability

The centennial volume of the State medical transactions of Connecticut contains many very interesting records of physicians and medical practice in the seventeenth and eighteenth centuries, and is among the first to gather and group this history in a permanent form

LOUISIANA QUARANTINE

The models of the Louisiana quarantine plant on exhibition in the Hygienic Department at the World's Fair are among the most interesting The present quarantine system of the State of Louisiana is based upon that inaugurated by Dr Joseph Holt in 1885, and consists of a complete plant for the fumigation and disinfection of vessels, together with the cargo and effects of ship, crew and passengers

The apparatus for fumigation consists of a furnace for generating sulphur dioxid, from which the gas is forced through a pipe leading to the bottom of the vessel The air used in the combustion of the sulphur in the process of oxidation is drawn from the ship's hold through a pipe whose extremity reaches just below the hatchway, thus drawing through the furnace and rendering innocuous the foul air of the vessel In addition to this apparatus, which is on the steam tug, there is a like supplementary apparatus fixed on a movable car on the wharf The disinfecting apparatus consists of two processes, that by steam and that by a solution of mercuric chlorid While a vessel is undergoing fumigation, either in mid-stream by the tug or alongside the wharf, all textile fabrics and baggage are disinfected by being placed in the heating cylinders These cylinders are eight feet in diameter and sixty feet long, and are three in number, thus providing ample accommodation for the disinfection of the largest steamship After the goods have been opened they are suspended on racks which are run into the cylinders, the heads of which are then closed and steam injected until the thermometer indicates a temperature of 220 degrees Fahrenheit, which is held for one-half hour, when the effects are removed

For the disinfection of furs, leather and rubber fabrics which would be destroyed by the heat, the mercuric solution is used, by means of hose with a spray nozzle which saturates them effectively

The present cylinders in use were the result of long and careful experimentation by Dr C P

Wilkinson, and differ materially from the original wooden chamber erected by Dr Holt

The furnace for generating the sulphur dioxid now used, is an improvement made upon the original by Dr S R Oliphant, and enables the production of a larger quantity of gas of greater proportionate strength than formerly While the system is the same as that adopted upon the original ideas of Dr Holt, the present plant with its improvements is far more effective and gives a greater guarantee of safety

Having had principally to deal with vessels from yellow fever infected ports, it is believed that the efficacy of the Louisiana system of quarantine has been fully demonstrated by its results, inasmuch as no case of yellow fever has occurred upon a vessel after disinfection (although many have been previously infected) and by the absence of the disease from New Orleans, a city which previous to 1879 was perennially infected with yellow fever

The establishment by Dr Holt of the present system inaugurated a new era in maritime sanitation Prior to this time detention, and an attempt at disinfection and purification without isolation was the rule, now detention is only required to as limited a period as is consistent with safety, careful inspection and thorough disinfection, purification and isolation The Marine Hospital Service immediately adopted the same plan with slight modifications, in fact all the maritime quarantines are practically carried on in like manner, and our coast defenses against the introduction of foreign pestilence are in excellent condition

A MODEL HEALTH PUBLICATION

For many years we have been in receipt of many sanitary publications, all of which are useful, many of them admirable, and some of them models, among the latter those of the Minnesota Board are fairly classed

The mortality report for instance, is based upon a careful personal review of all causes of death reported to the Secretary's office for the month to which it is is referred, and is collected to represent the actual population accounted for, and every fact, including individual causes of death, is carefully revised before publication

The Minnesota system of obligatory notification of infectious disease, and the monthly report of causes of death with obligatory notification of all deaths and their causes by medical men, is supplemented by an arrangement the Secretary, Dr C N Hewitt, has with Town Clerks and Health Officers to give the name and address of every physician in attendance upon a case of disease at death

This system is the outgrowth of six years of assiduous effort, the intention being to make this information available every month to Health Officers and physicians On page 66 of "Public Health" will be found in the "mortality record for August," one method of using this information

We reprint the September summary in the Miscellany pages of the Journal in this issue

RIGHT TO ESTABLISH HOSPITALS

An urban sanitary authority has recently purchased a building which it is proposed to convert into a hospital for infectious diseases, writes a subscriber to an English law journal of October 7 The building is not situate within the authority's own district, but in that of an adjoining authority The property owners in the neighborhood feel that their property will be seriously injured by the situation of the hospital, owing to a reasonable apprehension of risk, and interference with the pleasurable enjoyment of their houses for ordinary purposes Now what can be done about it? is the question asked in conclusion The sanitary authority of the district can not, as such, prevent the use of the building as a hospital, it is answered If the hospital can not be used without causing a public nuisance, the sanitary authority, or any owner of property, may maintain an action in the name of the Attorney-General for an injunction to restrain its use But such an action, brought in advance, it is said, has been rarely successful Of course if the hospital when opened is found to be a nuisance, any owner who is aggrieved may bring an action, and will undoubtedly obtain relief A number of decisions are cited in support of these statements, and much the same principles will be found to be true and applicable in this country

ARMY MEDICAL EXAMINING BOARD

The Army Medical Examining Board recently convened in Washington, D C, for the examination of candidates for admission into the Medical Corps of the Army has concluded its labors, with the result of adding five young officers to the Corps We learn that about forty candidates received invitation to appear before the Board but that only thirty-four took advantage of the permission Of ten examined during the first week one was successful, of fourteen who appeared during the second week none succeeded in effecting an entrance, while four of eleven in the third week were more fortunate in the effort to demonstrate their qualifications A notable percentage failed on account of defects of physique, and among these were probably some who might have showed to advantage had they been permitted to proceed with the examination into their general education and professional acquirements We print in another part of this issue, copies of some of the sets of questions used by the Board in the written examinations

THE NEW CURE FOR TUBERCULOSIS

Cures for consumption multiply as thick as the leaves in Vallambrosa, but the victims die as usual' The latest contribution to consumption cures is announced in a dispatch from Berlin to the effect that one DOCTOR J SUMMERBRODT is now curing tuberculosis by the administration of creosote It is well known that creosote is an anti-bacillary agent of high power, but we are sure that Americans will do well to await further particulars before going wild over this new-old discovery The memory of the Bergeron method, the stupendous failure of tuberculin, and the history of the myriad other failures, each heralded in its day as an unfailing remedy for the scourge, will operate to cause a suspension of judgment until results shall have finished the demonstration

THYROID GLANDS

Owing to the interest that has lately been shown in the use of thyroid glands in the treatment of myoxœdema, etc , and to afford physicians an opportunity of determining the value of this agent, Messrs Armour & Co, of Chicago, offer to supply gratis a small quantity of "Desiccated Thyroid Glands" to members of the profession, upon application, for experimental purposes The facilities of this firm for preparing the article are certainly unequalled, and the opportunity seems to us one which is worthy of attention, and which should be taken advantage of in the interests of medical science

MR GEO KEIL of Philadelphia is in Chicago this week, representing the S D Gross Monument Fund, and will call on the leading members of the profession in this city Twelve thousand dollars is the minimum amount required, and the raising of the amount should not be doubtful

Gentlemen desiring to anticipate MR KEIL's visit may leave contributions for him at the JOURNAL office, if more convenient

ASSOCIATION NEWS

Time of Meeting

OCTOBER 16, 1893

To the Editor —The next annual meeting of the Medical Society of the State of Washington was set for the first Tuesday in May, 1894, and I understand that the AMERICAN MEDICAL ASSOCIATION meeting is set for the same date I see that a change in the latter is contemplated Please let me know at the earliest date the time of the AMERICAN MEDICAL ASSOCIATION meeting at San Francisco, and we will arrange our meeting accordingly

Very truly, R L THOMSON, Sec'y

ANSWER —In order to enable State medical societies to send instructed delegates to the next meeting, prepared to vote on the proposed new constitution and amendments, a change of the date of the meeting has been proposed by a few members of the Business Committee A change in th time of meeting can only be authorized by the President, who has not yet issued the call

The Journal of the American Medical Association takes as much interest in pharmaceutical affairs as any medical exchange we receive No doubt the editor recognizes the close relationship which exists between the two professions —*Meyer Brothers' Druggist*, October, 1893

SOCIETY NEWS

New York State Medical Association

Tenth Annual Meeting —Held in New York, Oct 9, 10, 11 and 12, 1893

S B WYLIE MCLEOD, M D, PRESIDENT

INTRODUCTORY SESSION—MONDAY EVENING—OCTOBER 9

The President in his Address referred to the many important contributions that had been made by members during the past ten years, and the share each department had taken He said that although the Association was organized on Feb 4, 1884, it has at present eight hundred members, and a library of over nine thousand volumes

DR JOHN SHRADY of New York County, then delivered an address on

THE MEDICAL WORK OF THE ASSOCIATION DURING ITS FIRST DECADE

He referred to many of the more important papers and discussions such as, Dr Gouley's address on "The Nosology of Disease", Dr Janeway's address on 'Pathology", Dr A Flint, Jr's paper on "Some of the Relations of Physiology to the Practice of Medicine", Dr Van Zandt's paper on "Commercial Prescriptions", Dr McEwen's description of "The Mineral Waters of Saratoga", Dr Leale's article on "Nasal Feeding after Intubation", and many others A prominent feature of the work of the past few years is the practice, adopted from the British Medical Association, of having prepared discussions The first of these, which was proposed by Dr Flint, was on pneumonia They had proved very profitable

MORNING SESSION—FIRST DAY—TUESDAY—OCTOBER 10

DR JAMES G PORTEOUS of Dutchess County read a paper on the

PREVENTION OF DISEASE

in which he referred particularly to the many ways in which tuberculosis was spread abroad Milk is an important factor in carrying infection of various kinds What wonder that the medical profession is urging that dairies should be under strict medical supervision when those engaged in milking the cows are seen to dip their fingers into the pail of milk and wash off the udder of the cow, and by this repeated dipping of their fingers into the milk, remove both filth and disease from the cow and from their own hands, and deposit in the milk? In order to spread a practical knowledge of the dangers of tuberculosis, and the means of limiting its dissemination, the author is in the habit of distributing to his consumptive patients a printed card containing directions for their guidance, and also a reminder to the well persons with whom they are brought in contact He advises them to collect all sputa in a wide mouthed bottle, which is frequently washed out with hot water They are cautioned against spitting around promiscuously, and against kissing people, and they are urged to have separate table utensils, bed linen, table linen and beds Their friends are reminded that consumption is an infectious disease, communicated principally by swallowing the germs, by inhaling them, or by having them gain access to the system through wounds They are also advised not to kiss *any one* on the lips who has a cough

DR E D FERGUSON of Rensselaer County, read the next paper entitled,

AN ADDITIONAL NOTE ON NEPHROTOMY AND NEPHRECTOMY

He reported four cases illustrating the difficulties of diagnosis and treatment in this department of surgery, and called attention to the fact that in nine operations on such patients he had not found any evidence of tuberculosis being the cause of the trouble He thought the drainage tube of rubber which he formerly employed caused undue irritation, and therefore *preferred to use now a free incision* and packing so as to retain an open sinus for a long time

Dr John Cronyn of Erie County, cited a case illustrating the difficulty of diagnosis, and expressed the hope that in *the future the cystoscope* would render valuable aid in determining the true condition of both kidneys

Dr Thomas D Strong suggested that by supra-pubic cystotomy one could ascertain by inspection the condition of the ureters, and at the same time treat the disease of the bladder

Dr Ferguson said that as anything which is likely to aggravate the existing cystitis is liable to propagate the disease still further, he was opposed to the use of the cystoscope or to ureteral catheterization He would prefer to do an exploratory operation

Dr John W S Gouley of New York County, took the same position *An exploratory operation* has the advantage that if it confirms the diagnosis, a nephrotomy may be at once performed

Dr Nelson J North of Kings County, then read a paper in which he advocated the topical application of concentrated lactic acid to epitheliomata and cancroid ulcers This acid is not a caustic, but nevertheless seems to destroy the vitality of abnormal cells

Afternoon Session

Dr N P Dandridge of Cincinnati, read a paper on

THE SURGICAL TREATMENT OF PULMONARY CAVITIES

Such treatment he considered applicable to cases of abscess of the lung, gangrene, hydatid cyst and to tubercular and bronchiectatic cavities Such operations are not uncommonly done under the supposition that the case is one of localized empyema The cavity having been located by an aspirating needle, this needle serves as a guide for the knife After incision the cavity is best treated by packing it with iodoform gauze

Discussion on Lesions of the Pleura

Dr John Shrady of New York County, opened the discussion, propounding the following questions

Question 1—What are the factors of pleurisy? Its forms and contributive conditions? What are the pathological changes in a case of progressive pleurisy ending in recovery?

Question 2—What are the points of differential diagnosis in pleurisy and other affections of the chest?

Question 3—What is the treatment of empyema, with relative value of respiration, rib resection and free opening with tube drainage?

Dr Shrady said that the key to the diagnosis was usually furnished by the shifting line of dullness in the upper part of the cavity The indications for treatment are to limit the exudation at the beginning, allay pain keep the bowels free, and promote absorption When there is enough effusion of serum to produce intermittent orthopnea, or when the chest is half full, or when after a month there is no sign of absorption taking place, it is time to resort to the aspirator Aspiration is best *done in the sixth intercostal* space on the axillary line In cases of empyema if there is not sufficient space between the ribs for proper drainage a portion of the rib may be resected, and a drainage tube without lateral fenestra inserted, and sutured to the skin

Dr William McCollom of Kings County, in replying to the first question, said that pleuritic adhesions are found in about 50 per cent of the subjects examined *postmortem* He attributed much importance to the microbic theory of the origin of pleurisy and explained the apparently contradictory results of various observers by the different stages of the disease at which their investigations were made

Dr J Blake White of New York County replied to the second question He said that the pain of pleurisy is sometimes referred to the abdomen, and may therefore prove misleading Cough pain in the side and dyspnea, in the order named are developed in cases of tubercular pleurisy, but in other pleurisies *the pain* and dyspnea usually precede the cough When the patient shows a tendency to clear the throat frequently, and there is *nothing wrong* with the throat, it is safe to conclude that this symptom is indicative of pleuritic adhesions He did not believe that microbes had anything to do with the etiology of pleurisy

Dr J G Truax of New York County, in replying to this same question, said that the pleuritic friction sound is usually quite limited in area and changes its position frequently, it can be felt as well as heard

Dr Charles A Leale of New York County, answered *the third question by relating the histories of one or two* cases in his practice, in which, notwithstanding the severity *of the attack of* empyema, Nature *had succeeded in effecting* a cure without operative interference Incidentally, also, he gave an *illustration of the contagiousness of* pulmonary tuberculosis

Dr Thomas H Manley of New York County, thought the dangers of aspiration were not generally appreciated He stated that a review of his cases of thoracentesis showed that not one of them had lived after the operation more than three years

Dr Cronyn said he had been in the habit of using the aspirator *quite early in all cases of pleurisy with effusion*, and he had found this treatment only beneficial He would treat acute pleurisy by revulsives, such as dry or wet cups, at the beginning, followed by a cathartic, and afterwards by opium to relieve the pain Opium was preferable for this purpose to any of its alkaloids He did not favor rib resection in empyema, it was unnecessary He also called attention to the fact that consumption *might* be cured by metastasis, and cited a case under his observation, in which an attack of acute mania cured a pulmonary tuberculosis

Dr Donald McLean of Detroit, was also opposed to the use of the aspirator in the treatment of pleurisy, for it is rare that it willl completely empty a cavity He thought resection of the rib in empyema was extremely important, and in accordance with surgical principles

Dr Dandridge took the same position with reference to resection of the ribs, but he thought aspiration was of service in some cases as it produced a negative pressure in the chest and so aided lung expansion

Evening Session

Dr Austin Flint of New York County, presented a paper, entitled

REMARKS ON FERMENTATIVE DYSPEPSIA

As he was firmly convinced that fermentation in the alimentary *canal* is due *to microorganisms*, he naturally resorted to the use of various *anti fermentatives* and among these remedies he had found the subgallate of bismuth the best It is best given in capsules or tablet form, in doses of 5 grains *either* before or after each meal

Dr Cronyn thought that in those cases in which the author *had found this new* remedy so efficient, he would have found hydrochloric acid equally beneficial, for the condition calling *for* treatment is apparently one characterized by a deficiency of hydrochloric acid in the stomach

Dr Henry F Risch of Kings County, thought it was of the first importance in treating these cases of fermentative dyspepsia to ascertain whether the fermentation was due to decomposition of hydrocarbons or of nitrogenized substances If the product of the fermentation be carbonic acid gas, it is evident that the hydrocarbons are at fault, and this class of food stuffs should be eliminated from the diet Similarly if the odor of the patient's breath is foul, *the nitrogenized* substances should be withheld

Dr C Leale alluded to the great benefit that he had observed during the past summer in the St John's Guild Hospital, from lavage of the stomach and bowels in infants, and from the subsequent use of sterilized milk

Dr John A Wyeth of New York County, then read a paper entitled,

BLOODLESS AMPUTATION AT THE HIP JOINT, REPORT OF CASES OPERATED ON BY THE AUTHOR'S METHOD

This method was introduced by him to the profession in 1890, and since then he had been able to collect brief histories of thirty-nine amputations at the hip joint in which it had been employed In thirty five cases, it was done for disease, and in four, for very severe injuries Of the thirty-five, five died, and all of the cases of injury proved fatal

Morning Session—Second Day—Wednesday, October 11

Dr W D Granger of Westchester County, sent a paper on the

VOLUNTARY COMMITMENT OF THE INSANE TO ASYLUMS

He said that the modern notion is that asylums should really be hospitals, and the treatment should be individualized as far as practicable Many insane would avail themselves of asylum care if they could be voluntarily committed, and while several States had enacted laws permitting this, the patient after his commitment was treated about the same as those who had been placed in the asylum against their will The New York law now permits persons who are able to understand what they are doing, to voluntarily commit themselves to family asylums, but not for any specified time

Dr Gustavus Eliot of New Haven, Conn, read a paper on

THE TREATMENT OF ENTERIC FEVER,

in which he laid great stress on keeping every patient with typhoid fever, or any suspicious fever, in a condition of absolute rest, mental and physical, until thoroughly convalescent He advocated giving at the outset from 7 to 10 grains of calomel on alternate days for four doses, and subsequently' administering iodin or carbolic acid in very weak solution

Dr George Douglas of Chenango County, added still greater emphasis to the importance of absolute rest, as a life saving measure, and also favored the giving of two or three doses of calomel at the beginning of the illness He did not approve of the free use of alcoholic stimulants

Dr William Finder of Rensselaer County believed that food should be given sparingly during the early stages, and expressed his great faith in the efficacy of sulpho carbolate of zinc, as an internal antiseptic and astringent

Dr John H Martin of Otsego County, also indorsed the calomel treatment He fed his patients all through the disease, but was decidedly opposed to the use of alcohol in typhoid fever

Dr E R Squibb of Kings County, said that the favorable action of calomel in this disease was no doubt due to the fact that it is first converted into an albuminate, and is then slowly decomposed into the more energetic antiseptic, the corrosive chlorid of mercury

Afternoon Session

Sir James A Grant of Ottawa, Canada, in an interesting paper (which will appear exclusively in the Journal in full) on

RARE FORMS OF GOUT AND RHEUMATISM,

cited the case of a young girl who had all the usual symptoms of perityphlitis, until the sudden development of acute articular rheumatism in the joints of the upper extremities, when the abdominal symptoms immediately subsided

Dr Donald McLean of Detroit, then presented some interesting

SURGICAL AND PATHOLOGICAL MEMORANDA

Among other things he said that a large experience with ununited fractures had taught him that the chief cause of their non union was excessive violence at the time of the fracture He described his method of controlling hemorrhage in amputation at the hip joint by means of an aortic compressor He considers this method superior even to Wyeth's method

Discussion on the Treatment of Appendicitis

Dr Frederic S Dennis of New York County, opened the discussion, propounding the following questions

Question 1 —What proportion of cases of appendicitis end in resolution?

Question 2 —What class of cases require immediate operation?

Question 3 —What class of cases do not require immediate operation?

Dr Dennis said it was now generally accepted that about 50 per cent of cases of inflammation in the ileo cecal region end in resolution, and he did not approve of resorting to operation ordinarily until there had been a rapid pulse, a suppurative temperature, and intense pain for forty eight *hours without improvement The operation is not easy or* without risk, and it is very frequently followed by ventral hernia

Dr Gouley took the same position He related the histories of several cases which had recovered without operation, although at first apparently seriously ill Of course, where there is good evidence that perforation has taken place, immediate operation may save the patient

Dr McLean said the subject was weighed down with difficulties and responsibilities He could recall quite a large number of cases during the past two years where, despite the urgency of the symptoms, and the fact that no operation was performed, recovery was complete

Dr Joseph D Bryant of New York County, said that the relative frequency of foreign bodies in the appendix, in the two sexes, is about the same as the relative frequency of appendicitis in males and females, hence there is probably a close connection between the two facts and this is interesting from an etiological standpoint The symptoms of perforation are usually quite marked, and when present, indicate the necessity of immediate operative interference The presence of the "McBurney point" can only be considered as confirmatory of other signs, for the frequent and marked variations in the position of the caput coli show that no fixed point of tenderness can be looked upon as pathognomonic of appendicitis The existence of a tumor is also of but little assistance, for in about 14 per cent of cases the vermiform appendix is situated in the pelvis and in 20 per cent it is behind the caput coli He would lay more stress upon rigidity of the rectus muscle than he would upon an elevation of temperature as a guide to diagnosis and prognosis

Dr Wyeth said that all the disasters he had seen in this branch of surgery had been due to delay, and not to too early operative interference Again, the danger of ventral hernia is much less after an early operation

Morning Session—Third Day—Thursday, October 12

Dr Douglas Ayres of Montgomery County, read a paper entitled,

THE MALE CATHETER, WITH SOME OBSERVATIONS UPON THE PROPER MODE OF INTRODUCTION INTO THE BLADDER

He said that the proper and scientific use of the catheter demanded a practical application of the familiar anatomical knowledge as to the three great divisions of the urethra —the prostatic, the membranous, and the spongy portions While flexible catheters are often of service in cases where the urethra is unusually tortuous, the silver catheter, No 9 or 10 of the "American" scale, was his main reliance as he could more readily assure himself of the exact position of the instrument The patient should be placed in the recumbent posture with the thighs well drawn up and flexed, and the shoulders slightly elevated It is well worth remembering that the introduction of the catheter in difficult cases is often greatly assisted by pressing down the soft parts above the pubes, thus relaxing the suspensory ligament

Dr Gouley then exhibited an instrument of unusual historical interest—an exact bronze model of the catheter found in the ruins of Pompeii It has the sigmoid form, supposed to belong to a much later period, it is distinctly conical and has one eye, situated close to the vesical extremity He also exhibited a number of catheters of American manufacture, and stated it as his opinion that they excelled in finish those of all other manufacturers Even the cheap 10 cent catheter is made with an excellent finish He suggested that obstetricians should use these in their practice, for owing to their cheapness they can be thrown away after one using

Dr William Finder of Rensselaer County, read a paper on

THE EFFICIENCY OF VACCINIA AFTER TYPHOID FEVER

Some years ago he found that persons who had recently had typhoid fever could be vaccinated with the greatest ease and that they appeared to be no longer immune to smallpox He had had an opportunity to observe this curious fact on various occasions and he now made it a practice to re vaccinate people who had had typhoid fever since their last vaccination He presented these observations in the hope that other observers would either confirm or disprove the theory he presented that typhoid fever eliminated the protection produced by vaccination

Dr H Ernst Schmid in a paper entitled

REFLECTIONS ON THE NEED OF CLOSE OBSERVATION OF DISEASE AND UPON THE VALUE OF HYGIENIC THERAPEUTICS,

narrated some amusing anecdotes showing what wonderful results could be achieved, especially in the practice of medicine by attention to details Commenting on the uncertainties of medical science and art he asked what justice there was in a law which punished physicians for making pardonable mistakes and yet allowed the lawyer who loses his cases through like errors to go unpunished

Dr Darwin Colvin of Wayne County, reported a case of puerperal blindness, in which a liberal venesection shortly before confinement greatly relieved the patient and, in his opinion, prevented the occurrence of eclampsia, and perhaps other severe complications

Dr McGillicuddy said he had seen five cases of blindness occurring in connection with puerperal eclampsia, yet all recovered their vision without a resort to venesection, and in a paper entitled,

A PLEA FOR THE NON OPERATIVE METHOD OF TREATING DYSMENORRHEA, PELVIC INFLAMMATION AND PELVIC ABSCESS,

stated that he had found that the liberal use of hot water, by *mouth and by enemata, increased the portal circulation,* and so promoted the absorption of pelvic exudates Even when an operation becomes *imperative, this treatment* has put the system in a most favorable condition for operation

Dr Thomas D Strong of Chautauqua County was elected President for the ensuing year

---

Cedar Valley Medical Society —The following were elected officers for the ensuing year President, N S Pierce, Cedar Falls, Vice President M J A Mueller, Dyersville, Secretary and Treasurer W B Small, *Waterloo* Independence was selected as the place for holding the annual meeting next year

---

NECROLOGY

Dr G R Shaw at Antigo, Wis, October 12

Dr J W Green of Marengo, Ill, October 14

Dr W A Martin at Goshen, Ind, October 19

Dr Allan A Stevens at Sinclairville, N Y, October 13

Dr W H Thompson of New Haven, Conn, October 18

Dr J W Weatherford, Portland, Oregon September 20

Dr Justus Duffan of *Houston, at Austin,* Texas, *October 9*

Wm F Hutchinson —Dr Wm F Hutchinson died at Providence, R I, October 17 Dr Hutchinson lived in Minneapolis, 1870 to 1873 when he removed to Providence He was Assistant Secretary General of the Pan-American Medical Congress, and Vice President of the American Electro Therapeutic Association

Dr Moncrieff Drowned in Siberia —Word has been received here of the death of Dr D Scott Moncrieff, who was sent to Siberia under the auspices of one of the auxiliary congresses of the World's Fair The information came through Minister Dunn at Tokio, Japan who says Dr Moncrieff was accidentally drowned The State Department at Washington has also been notified —*Chicago Post*

Dr Algernon Sidney Coe of Oswego, N Y, died October 18 He was a surgeon of more than local prominence in the northern part of his State During the late war he served as surgeon of the 148th Regiment from August, 1862 to June, 1865, and did not lose a day in all those three years He was an alumnus of the College of Physicians and Surgeons, N Y, of the class of 1854

Dr John N Garnett, aged 73, died at Kansas City, October 14 Dr Garnett was born in Virginia He had been in Kansas City since 1879 and until of recent years had *practiced* medicine In his younger days he was a great sportsman and was known *as an expert with the gun* and rod Dr Garnett is the father of ten children, five of whom, three sons and two daughters, are still living His wife also survives him

Dr J S H Fogg died October 16 at his home in South Boston John Samuel Hill Fogg was born in Eliot, Me, May, 1826 He began the study of medicine with Dr Theodore Jewett in 1844, attending meanwhile the medical course of lectures at the Bowdoin Medical School, and later at the Harvard Medical School, at which place he took his degree in 1850 He at once opened an office in South Boston, where he remained until his death

In 1850 he married Sarah Frances Gordon, daughter of John Gordon, Esq, of Exeter, N H, who died in 1871 A year later he married Miss Mary G Clinch

Dr Fogg was a member of the Medical Society of Massachusetts, also a corresponding member of the Maine Histor*ical Society He was in the Massachusetts House of Representatives* in 1855, and was for some years on the School Board *of the city* He was a member of the Congregational Church

Dr John C Peters Passes Away —Dr John C Peters, the well-known authority on cholera, germ diseases and climatology, died on October 21 at his residence, "the Corners" at East Williston, L I He was 74 years old, and was stricken with palsy a short time before his death Dr Peters had practiced *medicine in* New York since 1842 He was born *in that city,* and educated at the College of Physicians and Surgeons and the *medical universities of* Berlin *and* Vienna. He was one of the founders and at one time president of the New York Pathological Society, and for many years was editor of the Society's proceedings He was the physician and personal friend of Washington Irving Dr Peters made a special study of Asiatic cholera and his library on cholera is said to be the most complete in the country He wrote many pamphlets on this subject He assisted Dr Edmund C Wendt in preparing a treatise on cholera, and in 1866 wrote Peters' "Notes on Asiatic Cholera," a standard work Dr Peters suggested new remedies in the treatment of consumption, Bright's disease and membranous croup

---

BOOK NOTICES

The Southern Surgical and Gynecological Association Transactions Vol V 1893

This volume of this handsome series contains an account of the proceedings and the papers read at the fifth session of the Association, held at Louisville, Ky, Nov 16, 17 and 18, 1892, under the presidency of Dr J McFadden Gaston of Atlanta The papers in the volume include articles by Drs Gaston, Brokaw, Haggard, Baxter, Dugan, McMurtry, Horace Grant, Ap Morgan Vance, Wm W Potter, R M Cunningham, Howard A Kelley, Cartledge, Myers, Lydston, Taber Johnson, Bedford Brown, Jas Evans, Coe, Simons, Chapman, Stone, our *omnipresent friend* H O Marcy, and others One of the most interesting papers is by Bedford Brown, 'Personal Recollections of the late Benjamin W Dudley of Lexington, Ky, and of his Surgical Methods and Work" Dr Brown was a pupil of Dr Dudley from 1846 until the conclusion of his medical education, and was therefore in a position to know the great pioneer surgeon thoroughly If it be true that "no man is a hero to his valet," it is equally true that the old-time preceptor was sure to be *the* great man of his age to his pupil The following announcement will strike many as a revelation 'In the use of sterilized water as a dressing for wounds he had an abiding faith, and used it to the exclusion of all other dressings Not a drop of *non* sterilized *water* was permitted to touch a wound He believed that unboiled well *or spring* water contained poisonous materials, *the* nature of which of course was not well defined in his mind He contended that the purest form of water, next to boiled or distilled water, was that from the cistern, which was used exclusively *for drinking* purposes in his family and office His use of boiled water in all wounds, except *those* healing by first intention, was profuse and abundant" Our space s not sufficient to quote further from this most interesting paper, and we rise from its perusal with greater admiration for the surgical methods of fifty years ago, and regret that there were not more Dudleys in that period, now growing misty with the lapse of time Of the other papers in the volume it is only necessary to say that they are replete with scientific interest The general appearance of the volume is highly creditable to the accomplished Secretary, Dr W E B Davis of Birmingham, Ala

A Text-book of Ophthalmology By WILLIAM F NORRIS, M D, Professor of Ophthalmology in the University of Pennsylvania, and CHARLES A OLIVER, M D, Surgeon to Wills Eye Hospital, Philadelphia In one octavo volume of 641 pages, with 357 engravings and 5 colored plates Cloth, $5 00, leather, $6 00 Philadelphia Lea Brothers & Co 1893

This work is divided into two parts, of which the first is by Dr Oliver and treats of embryology, macroscopic and microscopic anatomy, physiology, optics, physiological optics, examination of the eye, ophthalmoscopy, fundus reflex test, methods of determination of errors of refraction and accommodation, and correction of errors of refraction and accommodation

The painstaking care with which the author has developed every detail of his subject, has produced a work which leaves little to be desired, there is no padding or redundancy, and there is an earnestness born of an intimate knowledge of the subject and a sincere desire to convey instruction

The second part of the work, by Dr Norris, treats of the diseases and injuries of the eye, the eyelids and the orbit, including the affections of the optic nerve and its internal prolongations The concluding chapter describes some of the more common and important operations on the eye In this section the same care has been taken to prune superfluities, and secure precision, as in the first, but naturally the author has more latitude of expression, owing to the nature of his subject

The illustrations are excellent and the typography good

Anatomy, Descriptive and Surgical By HENRY GRAY, F R S Lecturer on Anatomy at St George's Hospital, London, New American from the thirteenth enlarged and improved English edition Edited by T PICKERING PICK, F R C S, Examiner in Anatomy, Royal College of Surgeons of Eng and In one imperial octavo volume of 1,100 pages, with 635 large engravings Price with illustrations in colors Cloth, $7 00, leather, $8 00 Price with illustrations in black Cloth, $6 00, leather, $7 00 Philadelphia Lea Brothers & Co 1893

This well-known work on anatomy which has been the principal text-book in England and the United States for the last thirty-five years, has again made its appearance in a new edition, this time wholly English The Holden's Landmarks incorporated in the last edition have been omitted The changes have included the latest teachings on general anatomy and the development of the tissues No recommendation of ours could add to the already high estimation in which this book is held by the profession in America It has sometimes been said that there were many errors in Gray, but nevertheless they have grown fewer with each successive edition, and it takes such a hypercritical vision to discover them now, that like the spots on the sun the average man only knows of them from hearsay

A Hand book of Ophthalmic Science and Practice By HENRY E JULER, F R C S, Ophthalmic Surgeon to St Mary's Hospital, Surgeon to the Royal Westminster Ophthalmic Hospital, London New (second) edition, revised and enlarged In one octavo volume of 562 pages, with 201 engravings, 17 colored plates, test types and color blindness test Cloth, $5 50, leather, $6 50 Philadelphia Lea Brothers & Co 1893

This well-known work contains concise descriptions and typical illustrations of the important affections of the eye The different structures are treated of seriatim, commencing with the eyelid, and concluding with a chapter on diseases of the orbit The most extensive chapter in the book is that devoted to normal refraction and errors of refraction The consideration of the diseases of each structure commences with the anatomy and physiology of the part The illustrations are much better than are usually found in manuals of this character, and the colored plates are fine specimens of the chromo lithographic art In the appendix will be found useful formulæ, reading tests and test types

Essentials of Bacteriology Being a Concise and Systematic introduction to the study of microorganisms for the use of Students and Practitioners By M V BALL, M D Physician to the Eastern State Penitentiary at Philadelphia Second edition, with eighty-one illustrations, cl 16 mo pp 205, Philadelphia W B Saunders 1893

This little book having passed to its second edition, has its success assured in advance Bacteriology has made such rapid changes in the last year that a work on the subject needs frequent revision to keep in touch with the new discoveries The author says "In this second edition the results of last year's earnest work have been embodied The separation from the blood of antitoxines, and their application to the cure of disease will probably revolutionize our present method of treatment, and add some peculiar agents to our materia medica The question of immunity is still unanswered, though the phagocytic theory of Metschnikoff and the Alexines of Buchner are bringing us to the solution Upon these lines the greatest efforts are at present being made"

Johns Hopkins University, Baltimore Studies from the Biological Laboratory Vol V No 4 Baltimore 1893 Price $1 00

The contents of this volume are, 1, An undescribed Acranate by E A Andrews, 2 Contributions to the Embryology of Chiton, by Maynard M Metcalf, 3, The formation of the so called Cypress knees on the Roots of the Taxodium Distichum, by John P Lotsy, 4, On the Origin and Development of the Stichidia and Tetrasporangia in Dasya Elegans, by B W Barton This volume is edited by Prof H N Martin and Prof William K Brooks

Asiatic Cholera Its genesis, etiological factors, clinical history, pathology and treatment By JOHN A BENSON, Professor of Physiology and Associate Chief of the Department of Medicine, College of Physicians and Surgeons, Chicago Chicago The J Harrison & White Co 1893

This is a book of 248 16mo pages, in which the author has compiled in a series of lectures to his class, the essentials of the current teaching in regard to cholera It is well written and has been brought up to date The illustrations are cheap and poorly done, but as a whole the book is to be highly commended

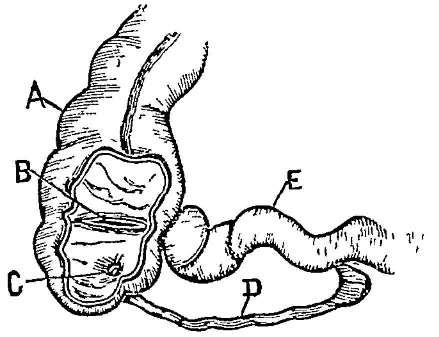
Minor Surgery and Bandaging By HENRY R WHARTON, M D, Demonstrator of Surgery in the University of Pennsylvania In one 12mo volume of 529 pages, with 416 engravings, many being photographic Cloth, $3 00 Philadelphia Lea Bros & Co 1893 Second Edition

There is little change in this work from the original edition published in 1891 The author says "The aseptic and antiseptic methods of wound treatment have been thoroughly revised, and a considerable number of new illustrations have been added"

SELECTIONS

Abnormal Appendix Vermiformis —So much surgical work is being done to day upon this part of the intestine that the following anomaly is worthy of notice the subject, a native of Germany, had died at the age of 63, of phthisis In dissecting the region of the cecum, I found the appendix beginning by a funnel-shaped opening at its lower and posterior portion, thence running over the brim of the pelvis, and terminating in a cul de-sac, which opened into the ileum about three and one half inches from the ileo cecal valve

Its appearance was smooth and bluish pink, about the size of a lead pencil, and measured six and one half inches in length It readily admitted a good sized probe at its termination in the ileum which passed into the cecum, There was no evidence of previous inflammation, and its mucous membrane seemed to be continuous with that of the ileum



A—Colon B—Ileo cecal valve C—Orifice of appendix D—Appendix E—Ileum

The specimen (which the accompanying engraving shows about one-fourth the natural size) may be seen in the museum at Cooper Medical College —Lawrence Boido, S B, in *Occidental Medical Times*

Hard Times and Free Medicine —From every part of this great and rich country, the news comes to us of extreme stringency in the financial position of our confrerés, the general practitioners Never was there a richer opportunity for the masses to play the pauper than now The present panicky state of the money-market affords people an immense excuse for wholesale imposition on the profession The conditions of the times will not give them free bread, free clothes, free transportation on the railroads or rent free, but they hie away to many of our too numerous hospitals and dispensaries for free treatment—advice, medicine and all included for nothing, or for “ten cents”—the figure fixed in certain palatial infirmaries

The consequence of all this has been most demoralizing to the profession and the public Practitioners reduced to a state of enforced idleness and grim want, are forced either to quit their profession altogether, or to “mee *steal* with steel,” to open rival dispensaries, to advertise, or to drift into downright quackery

Many cases have come to our knowledge which go to prove that the practice in vogue in many of our largest dispensaries is a species of downright robbery, and tends to work incalculable harm to the profession Case after case is taken from among people of ample means and turned over to the hospital or to the college professor for his clinic, without a word being asked as to their mendicity or ability to pay anything at all Cheap railroad excursion rates drain the outlying villages for miles in every direction

This hydra headed monster of indiscriminate free treatment must be seized and strangled, or we will soon see the profession of medicine dragged in the dust, open downright quackery will be rampant, and integrity and honor in the healing art will be things of the past

By no means let us withhold our services to the poor and deserving, for humanity compels us to gratuitously attend those without means Nor let us strip the field of such clinical material as legitimately belongs to the teacher, but let the teacher not forget that he has no prescriptive right to filch from the struggling practitioner what justly belongs to him —*Medical and Surgical Reporter*, Oct 21, 1893

Relative Values of Meat Extracts —In the *Public Health* for September, 1893, we find the results of an official analysis of several extracts of meat, made by Mr Tatlock, the public analyst for the city of Glasgow These studies form a part of the annual report of the Chief Sanitary Inspector, Mr Fyfe The desiderata now aimed at in the preparation of these food stuffs are, 1, a concentration or freedom from water, as great as possible, 2, freedom from fat, 3, palatability It is an error, held by very many that a given weight of meat extract may contain many times the nourishment of the same weight of meat This can not be, since no extract can possibly hold more than the total soluble parts of the beef, which are not more than one fifteenth part of the weight of beef itself The table given below contains a comparison regarding four specifically named extracts, and the analyst introduces his table with the following remarks

“In making a comparison of the relative values of these samples, it is only necessary to determine how far they comply with the above requirements Bovril does this within 20 per cent, but it is but fair that allowance should be made to this extent for water necessarily present to keep the extract in a soft state Liebig’s also complies with these conditions and even more closely, as this extract shows little over 10 per cent of water, but it is an extra dry one Valentine’s, containing as it does over 50 per cent of water, does not fulfill these conditions, so that after allowing for 20 per cent water, it might well be 30 per cent stronger Brand’s extract is scarcely an extract at all in anything else than the name as is obvious from the fact that it contains over 90 per cent of water, so that after allowing for 20 per cent water it might contain 70 per cent more dry extract of beef ”

	Per Cent			
	Bovril Fluid Beef	Liebig Co ’s Extract of Meat	Valentine’s Meat Juice	Brand Co ’s Essence of Beef
Water	20 42	10 79	51 40	90 48
Ether Extract	0 56	0 08	0 04	Trace
Albumen, Peptones and Gelatines	14 67	17 60	7 66	4 83
Creatine and Nitrogenous Extractives	37 01	42 20	18 56	2 98
Non Nitrogenous Extractives	8 00	8 59	11 96	0 47
Mineral Matter	19 34	20 74	10 38	1 24
	100 0	100 0	100 0	100 0
Total Solids	79 58	89 21	48 60	9 52
Weight of Sample	2 ozs	2 ozs	2⅓ ozs	2¾ ozs
Ounces of Meat from which the total sample is Derived	24 6	27 6	17 5	4 1

MISCELLANY

New Medical College —The trustees of the Kansas Medical College met at Topeka, October 9, and voted to erect a new college building Francis Storrs, M D, was elected Instructor in Latin and G L Beers, A M, M D, Professor of Materia Medica and Therapeutics

Sir Andrew Clark —This well-known London physician was stricken with paralysis while talking with a patient, October 19 He was born Oct 28, 1826, and was graduated in Edinburgh The attack, in view of Sir Andrew’s great age, is considered serious

New York Post-Graduate Hospital —In the Court of Common Pleas, Judge Bischoff denied an injunction *pendente lite* applied for, to stop the erection of the new structure at the corner of Second Avenue and Twentieth Street The Court held that as the old structure had been occupied for many years for hospital purposes, without becoming a nuisance, the new building should be permitted to proceed

New Pasteur Institute at New York —On October 9 a handsome new structure was formally dedicated to this institution The building is of stone and brick, five stories high, and contains every appliance indicated by modern ingenuity for the relief of hydrophobic sufferers It is located at West Central Park and Ninety seventh Street It will remain under the control of Dr Paul Gibier formerly the Assistant Professor of Pathology at the Paris Museum, and since 1889 a resident of New York city The address on this occasion was delivered by Dr Ogden Doremus, who pointed out the necessity of supporting complete laboratories and infirmaries for those unfortunates who seek the Pasteurian treatment, and on account of diseases of the nervous system The private means of Dr Gibier, together with a few contributions from sections where the good results of the treatment have been gratefully recognized, are the sole source of present support Neither city nor national legislators have felt impelled to give any vote of assistance to this beneficent undertaking

Hospital Change —The patients were removed from the old City Hospital to the new hospital at St Paul, October 16

New Hospital at Lincoln, Neb —The Cottner Medical College has established a hospital in connection with their institution

Hospital for the Insane, Middleton, Conn —This institution is to have an annex at a cost of $100,000 that amount having been appropriated by the last Legislature

New Hospital at Champaign, Ill —A new hospital is to be established at Champaign, Ill A banker of that city starts the subscription with a check for $10,000

Proposed New Hospital, Chillicothe —The physicians of Chillicothe Ohio, E F Waddle, J M Leslie and others have urged upon the city authorities the establishment of an Emergency Hospital at Chillicothe

Foundling Hospital Closed —The San Francisco authorities have closed the Foundling Hospital on account of alleged mismanagement The infants still alive in the institution were handed over to the Sisters of the Good Shepherd

New Hospital at San Francisco —The new hospital annex of the Cooper Medical College of San Francisco will be opened some time next summer The building will cost somewhere in the neighborhood of $150,000 and will have a capacity of 100 beds

Landgraf Home and Hospital —Articles were filed in the County Clerk's office October 18, establishing the Alma Landgraf Home and Hospital of New York city The trusttees are Alma and John Landgraf, Runegrunde Sulzer, Mary Mecker, Emma and George Schmidt and Charles, Matilda and John Morgan

The Board of Managers of the Chester, Pa, Hospital met October 10, and in addition to reelecting the old officers of the Board, appointed the following medical staff for the ensuing year Drs J L Forwood J T M Cardeza, W B Ulrich, F F Long, S R Crothers, F R Graham, Ellen Brown, Hannah J Price, D W Jefferis, J M B Ward Drs Cardeza and Ward are new members of the staff, and take the place of Drs J Frank Evans and C W DeLannoy

Choked by a Sponge —A patient at St Joseph's Hospital, Syracuse, N Y while undergoing an amputation October 17, the throat filled with mucus and an attempt was made to clear the fauces by sponging The sponge slipped from the forceps and was drawn into the trachea by inspiration Tracheotomy was immediately performed and the sponge extracted, but the patient was fatally asphyxiated and did not rally

New Laboratory —The bacteriological laboratory of the Postgraduate Medical Department of the University of California is now fully equipped and ready for students It is under the direction of Dr John C Spencer, and is one of the most complete of its kind in the West

Dr S O L Porter, for the past eight years Professor of Practice at the Cooper Medical College has resigned his chair

The Charleston Medical College opened October 16 with an increased attendance over last year Dr F L Parker gave the opening lecture

Appointments —Drs Wm P Northrop, S T Armstrong and Albert I Swan have been appointed visiting physicians to the Contagious Disease Hospital on North Brother Island, N Y

The Schoolmaster Abroad —The Medical Practice Act of Connecticut, took effect October 1, and applicants for registration are numerous The following are reported as among the applications recently received, from which it would appear that the Examining Board has not commenced its labors too soon

'I taught first when I received your notice that your board did not register vetenary surgean, but I lernt cence that you do I practic foure years under other Doctors and Three years alone before I came to this state I have been Two years in this state I did not state that I had practiced in this state on the blank because I did not have an office her altho I have practice I have had at anavrag one case a week cence I have been hear"

Another produced the following

"I write to you to see if I can get a permit to put up a Blood medison maid of Herbs this has been my business for year and I intended to have wrote to you befour this but I have had a sick Lady to see to so I have not had time"

Both of these epistles were received from residents of the same town

Alvarenga Prize of the College of Physicians of Philadelphia —The College of Physicians of Philadelphia announces that the next award of the Alvarenga Prize, being the income for one year of the bequest of the late Senor Alvarenga, and amounting to about one hundred and eighty dollars, will be made on July 14, 1894, provided that an essay deemed by the Committee of Award to be worthy of the prize shall have been offered

Essays intended for competition may be upon any subject in medicine, but can not have been published, and must be received by the secretary of the College on or before May 1, 1894

Each essay must be sent without signature, but must be plainly marked with a motto and be accompanied by a sealed envelope having on its outside the motto of the paper and within it the name and address of the author

It is a condition of competition that the successful essay or a copy of it shall remain in possession of the College, other essays will be returned upon application within three months after the award CHARLES W DULLES, Sec'y

Sanitation Mass Meeting —A sanitation mass meeting was *held in San Francisco on the 3d inst to consider leading* questions of sanitary reform The attendance was a large and enthusiastic one, and the meeting was addressed by leading physicians and citizens Dr Winslow Anderson, a member of the State Board of Health, read an able paper on "Filth Diseases Cholera Diphtheria and Typhoid Fever" He referred to the thoroughly organized defensive campaign of the Board of Health against any possible invasion of cholera "Inspectors," he said, "are ready at an hour's notice to go to any point of ingress on our borders, there strict quarantine will be observed, every case will be isolated disinfected, guarded We have the hearty cooperation of our chief executive, of all the railroads, and ample funds at our command should the emergency arise" Dr Anderson warned his listeners against over confidence in the peculiar situation and favorable atmospheric conditions of San Francisco, citing the great epidemics in Sweden and Russia as evidence that immunity from cholera is not dependent upon conditions of climate His advocacy of a new sewerage system for the city was enthusiastically received Matters of such grave moment to the people *should not be left, he said, to* supervisors and political jobbery, but to a board of men skilled and experienced in sanitary science

Choking to Death —A policy of accident insurance covered only injury or death received through external, violent and accidental means The insured lost his life by eating a piece of beefsteak that, in the attempt to swallow, accidentally passed into his windpipe, choking him to death in a few moments *That the policy covered such death was of course* denied by the insurance company But the Court of Appeals of Kentucky in a decision rendered Sept 16, 1893, (Amer Acc Co v Reigart, *23* S W Rep 191) holds otherwise *It says that it was only required that the means or* that which caused the injury should be external, and not that the injury should have been external, and that when the substance causing the death was visible and placed in *the mouth of the assured,* lodging by accident in the windpipe, instead of the stomach producing injury or death, it was as much an accident as if he had taken arsenic under the belief that it was some harmless medicine, which the authorities hold renders an insurance company liable While a *violent death,* as the term is used, is simply an unnatural one,—a death not occurring in the ordinary way

Must have a License —The Health authorities of Philadelphia have given notice that lying in hospitals in that city must hereafter comply strictly with the law, and such institutions must take out a license

The law passed by the Legislature and approved by the Governor was prepared by the Pennsylvania Society for the Protection of Children from Cruelty Its expressed purpose is to keep lying-in houses within sight and prevent malpractice and criminal operations at so-called maternity hospitals Major Veale, Chief Medical Inspector Taylor and Secretary Crew, of the Children's Society, are determined *to have the law's provisions carried into effect*

In order to secure a license application, in writing must be made *to the* Board of Health, to which the names of six reputable citizens must be appended testifying to the *respectability of the applicant* The house named is then to be visited by Chief Medical Inspector Taylor, who reports *to* Health Officer Veale, after which the Board of Health takes action The license is for two years, for which a fee *of $5 is charged*

Licensed institutions are furnished with blanks on which all cases looked *after are to be reported to the Health Office,* showing the name and residence of the mother, the date of birth of the child and the time and place of removal of the child

Public Health in Minnesota —September, 1893 The mortality record for August, 1893 (see page 72) 1,021 deaths is noteworthy as larger than the average of the same month for the last six years (1,016 8) and greater than the record of this month in any of those years except 1888 (1,415)

Looking for the cause—*Tuberculosis*—was much in excess of the average (109—92 5) and greater than the same month in any year except 1890 (115) *Enteric Fever* greater than the average of six years (48—30 5) or the same month of any year since 1887 *Diphtheria* was in excess of average of six years (30—31) and only exceeded by the record of 1888 and 1890 (40—38) Other diseases of the list are notably less than the average, but *Diarrheal Diseases of Children* caused greater mortality than for the same month in last six years, except 1888 (260 379) *Pneumonia* was much below the average of six years There has been a steady decline in the mortality from this cause *in August, since 1887 (31, 18 16, 14, 12, 11)* and the same is true of *Bronchitis* (13, 12, 11, 11, 8, 5)

Enteric (Typhoid) Fever made the following mortality record in 1892 as compared with 1891 and the average of six years (1887—1892)

DEATHS PER 100,000 OF POPULATION
Average in six years

	1891	1892	Avg of 6 yrs
State at large	41	30 9	42 32
Cities over 35,000	55 3	47 4	69 5
" 15,000 to 35,000	146 1	87 7	118 8
" 5,000 to 15,000	56 2	36 8	41 1
Cities and Villages under 5,000	29 4	21 8	29 8

In other words the mortality from enteric fever in 1892 was less in all classes of our population than in 1891, and than the average of six years It is but just to give separately the rates of the two cities which make up the second class (Winona and Duluth)

DEATHS PER 100,000 OF POPULATION

	1891	1892	Avg of 6 yrs
Duluth	214 3	123 82	172 1
Winona	21 9	21 9	20 14

Winona is located on a sandy gravel through which passes the cold and hard spring water from the high land to its rear, and the problem of disposing of excreta and garbage has been a *comparatively easy one,* as has *the introduction* of public water supply and sewer system Besides it has had for years a well equipped and active Local Board of Health and under the direction of Dr Franklin Staples as Health Officer

Duluth on the contrary is literally founded on rock, so that the introduction of public water supply and construction of sewers has been a very expensive and tedious labor The population in a limited area has increased with great rapidity and the city has, besides, to accommodate a large *floating population going* and *coming* from the mines and lumbering camps Despite these natural difficulties and secondary causes of enteric fever, under the vigorous and intelligent direction of the present Health Officer, Dr W G Goffe, the work of sanitary improvement has begun a marked and steady *reduction* of mortality from this cause, e g , the annual mortality for 1892 was 123 82 per *100,000 of* the population as compared with 214 3 in 1891

THE PUBLIC SERVICES

Army Medical Examination Papers at the Recent Examinations

ARITHMETIC

1 When the divisor and quotient are given, how can you find the dividend?

2 How many inches are there in 0625 of a yard?

3 What is the interest on $865 32 for 1 year, 3 months, 10 days at 7 per cent?

4 If 1 5 pounds of sugar cost $0 023 what will 25 pounds cost?

5 How many grammes are there in 7 2-5 pounds avoirdupois?

6 *Illustrate the* six principal forms of triangles

GEOGRAPHY

1 Give the boundaries of Italy by land and sea

2 Name the principal rivers *of India*

3 Through what States would you pass, going from St Louis to Mobile?

4 Bound Minnesota and name the capital

5 Through what States does the Connecticut River flow

6 Name the provinces of British America

7 Name those parts of the United States *where the* rainfall is unusually large

8 Give an outline of the indications useful in weather predictions in the Eastern United States

HISTORY AND LITERATURE

1 From what power was Louisiana purchased and in what year?

2 State what you know of the battle of Palo Alto

3 Who composed the first Roman triumvirate?

4 When and with whom did the Plantagenet line of English *sovereigns begin and end?*

5 What historian has the United States produced? Name at least one work of each

6 In what works do the following characters appear Ichabod Crane, Uriah Heep, Colonel Newcombe, Falstaff?

7 Who was Poe? When did he live and what did he write?

8 Mention the principal authors contemporary with Queen Elizabeth

PHYSICS

1 *What* is the mechanical principle of the pulley? What advantage is gained by use of a single pulley? What by a series of pulleys?

2 What is meant by the pressure of the atmosphere? Under what conditions does it vary?

3 What is an artesian well? What principle of hydraulics does it illustrate?

4 What fundamental laws of light are illustrated *in the* action of lenses?

5 What are the peculiar features of an insular *climate* and how are they explained?

6 Briefly explain the principle of the electric telegraph

CHEMISTRY AND TOXICOLOGY

1 What is meant by catalytic action? Give an example of this action

2 What is the atomic weight of sulfur? From what place is the sulfur of commerce chiefly derived? What is the symbol of the gas which it forms by its union with hydrogen gas? How is this gas prepared?

3 What is bleaching powder? What is its chemical symbol? How is it prepared?

4 Describe the chemical action which takes place when fragments of iron wire are dropped into hydrochloric acid When they are dropped into sulfuric acid When they are dropped into nitric acid

5 What conditions are necessary to the process of alcohol fermentation? Describe the process What are its products?

6 Describe briefly, Reinsh's test for arsenic

MATERIA MEDICA AND THERAPEUTICS

1 Give a brief account of the physiological action of atropin, and mention the diseases in which belladonna has been employed Give officinal preparations with doses

2 Contrast the physiological effects of the three most important anesthetics How are they supposed to act, and what are their relative dangers?

3 Enumerate the salts of potash employed as medicines Give dose and brief therapeutic indications for each of them

4 Mention the remedies which produce vasomotor paralysis as well as those which have the opposite effect

5 Give physical characters, source, solubility, dose and brief therapeutic application of aconitin, amyl nitrite, acetanilid, antipyrin and aristol

PHYSIOLOGY AND MEDICAL JURISPRUDENCE

1 Draw a diagram of the lateral surface of the left cerebral hemisphere (human brain) marking out carefully the cortical areas

2 Describe the minute structure of voluntary and smooth muscle, and state what physical and chemical changes take place in muscle during contraction

3 Describe the part taken by the pancreatic juice in the digestive process

4 Mention the important waste products of the body, give the quantity of each daily excreted, and state what organs are concerned in their elimination

5 In conducting an examination of the dead body of a newborn child, what circumstances would lead you to the opinion that the child had been born alive? What does the term, "born alive," imply in a legal sense?

ANATOMY

1 Describe the phrenic nerve, its origin, course and relations to other organs How does the right nerve differ from the left?

2 Describe the origin, course, distribution and exact relations of the median nerve

3 Describe the posterior tibial artery and its exact relations

4 Describe the popliteus muscle and its exact relations

5 Describe the ulna Give its relations in the arm Locate the areas of attachment of the muscles that arise from or are inserted into it

SURGERY

1 What is traumatic fever? How and under what circumstances does it occur and what causes it?

2 How do wounds heal? (Take this subject and write a brief account of what you know about it)

3 What are the symptoms, etiology and treatment of phlegmonous erysipelas?

4 What are some of the latest views on the surgical management of aneurism?

5 Describe some of the principal amputations done upon the foot, with illustrative diagrams

PATHOLOGY AND BACTERIOLOGY

1 Describe the microscopic appearance of a tubercle give its mode of formation and the subsequent changes which it may undergo

2 What pathological changes would you expect to find in the lungs liver, spleen and kidneys, in a case of long-standing obstructive lesion of the heart?

3 Give the histological characters of sarcoma

4 Mention several of the most important discoveries made in bacteriology during the period, 1880–1893

5 Describe the morphological and biological characters of streptococcus pyogenes What diseases are caused by this organism?

HYGIENE

1 What are the forces which occasion an upward movement of the air of a room or ward, through a ventilating shaft extending from the ceiling to beyond the ridge?

2 What kind of water or class of waters act most readily on lead pipes? What are the prominent symptoms caused by the continued use of water contaminated with lead? Could you discover whether lead was present in a given water? If so, describe the experiment by which you would discover its presence

3 What is meant by the siphonage of a water trap? How is it prevented?

4 Why are starchy and saccharin articles of food such as arrowroot, tapioca, etc , used so largely in the diet of sick persons?

5 What diseases or diseased conditions are usually attributed to exposure to sewer air? What are the constituents of sewer air, and which of them are the active agents in the production of the diseases you have mentioned?

PRACTICE OF MEDICINE

1 Give the clinical history and differential diagnosis of acute miliary tuberculosis

2 State briefly the causes, diagnosis, symptoms and treatment of acute pericarditis

3 What are the varieties and causes of jaundice?

4 What, briefly, are the causes, symptoms and treatment of acute nephritis?

5 What are the principal forms of insanity? What are the characteristic symptoms of, and what the prognosis in melancholia?

6 Describe the clinical course of a case of leprosy

OBSTETRICS AND DISEASES OF WOMEN AND CHILDREN

1 Presentation and position and relative proportions of maternal and fetal parts being normal, what causes may delay labor? Indicate treatment of one

2 Under what circumstances should version be performed? Briefly give method

3 What are the symptoms of placenta previa? How would you treat a case?

4 What are the supposed causes, the symptoms and the treatment of chlorosis?

5 What affections are liable to demand attention at the menopause?

6 What abnormal conditions, besides suspended animation, may require treatment in a newly born infant? Selecting most common, how would you treat it?

Army Changes Official list of changes in the stations and duties of officers serving in the Medical Department U S Army, from October 14, 1893 to October 20 1893

First Lieut A N Stark Asst Surgeon, now at Ft Clark Texas, will proceed at once to Ft McIntosh, Texas, and report to the commanding officer *for temporary duty with troops in the field at Carrizo Texas*

First Lieut Robert S Woodson Asst Surgeon U S A now temporarily at Ft McPherson Ga will return to his proper station Ft Barrancas Fla

First Lieut Merritte W Ireland, Asst Surgeon (Ft Apache Ariz Ter) is granted leave of absence for one mouth to take effect about the 20th inst

ADDRESS

ADDRESS ON GENERAL MEDICINE

Read at the Meeting of the Mississippi Valley Medical Association, held at Indianapolis, Ind , Oct 12, 1893

BY JAMES F HIBBERD, LL D, M D
RICHMOND IND

Mr President —I purpose to call attention to four points in general medicine that seem to me to deserve a rehearing, more familiarity with which, I think, promises us higher satisfaction with ourselves and larger usefulness to our clients These points are

Progress of preventive medicine, biological law in its relation to medical science, cell place and power in structure and function, mind influence in pathology and therapeutics

On these points I present my individual views, I am not a teacher nor an expert student, have no authority to speak *ex cathedra* and do not assume it

PROGRESS OF PREVENTIVE MEDICINE

Preventive medicine in its wider sense includes all measures to maintain health instituted under hygienic regulations and sanitation, but I shall content myself on this occasion by reference to the management for the suppression of contagious diseases

ON CHOLERA PREVENTION

Ten years ago the only known means of preventing the invasion of any country or city by cholera was to exclude every person and thing contaminated by the germs of the disorder In 1884 cholera was epidemic and severe in Egypt, and was soon transported to southern Europe Germany, England, France and Italy each appointed a commission of practical medical men and expert bacteriologists to inquire into the nature of the malady, and devise means of prophylaxis No better illustration of the rapid progress of preventive medicine and the manner of that progress can be desired than a study of the methods of investigation pursued by those commissioners and the formulated results of their labors Their investigations began in Egypt, continued in Europe and were completed in India, where cholera has its continuous renewal and perpetual home The results of their labors were not entirely harmonious at first, but the unequaled Koch, at the head of the German commission, made a detailed report of the work and established the facts, the accuracy of which has been conceded by all parties

Accordingly, we now know that the cholera germ is the spirillum choleræ Asiaticæ—commonly called the comma bacillus of Koch—that it is found in the human body only in the intestines of its victims where it multiplies rapidly, that it is not communicated directly from person to person, but the alvine evacuations of the victims find their way, generally through water, into the bowels of susceptible persons, who then become additional victims, that this germ also finds a breeding place in damp soil and in stagnant pools and in running streams containing organic matter, and survives in pure water but does not multiply there, that it is virile only within narrow thermal limits, that it holds its life by a frailer tenure than any other equally prolific and destructive pathogenic spirillum, being quickly destroyed by the official germicides, by drying, by acids, and by a temperature below 56 degrees or above 126 degrees Fahrenheit

It is the application of this exact knowledge that has confined the cholera to the quarantine dominions at New York, thus preventing its diffusion in the United States, and it is a like application of this knowledge that has, on sundry occasions and at divers points in England and on the continent, enabled the authorities to confine the Asiatic plague to the single case in which it was discovered And, per contra, it is ignorance of these established facts, or failure to use them, that permits the ravages of cholera at this time in Arabia, in Russia and on the shores of the Mediterranean

Every practitioner of medicine in this country should feel it an obligation to constitute himself a propagandist of the knowledge of the means of prevention of cholera among the populace, and when the people are thoroughly informed in this behalf and join intelligently and heartily with the health authorities in recognizing and managing the first case that may appear in any locality, the disease will be stamped out at that point and then cholera can never again become epidemic in the United States

YELLOW FEVER

Yellow fever is another scourge that has been and still is being much studied, not with such satisfactory results touching the nature of its course as with cholera, but enough has been determined in regard to its nature to warrant the declaration that it can be stamped out at any point where it may appear. All that is necessary to protect us from further invasion of yellow fever is the watchfulness, the intelligence, the skill and the devotion to duty everywhere that has been so successfully exercised for eight years by the health authorities at New Orleans,

It is known that yellow fever is an exotic in the United States, and that it comes to us almost exclusively from the inter-tropical islands and mainland on the eastern border of the Western Hemisphere, and it is a reasonable anticipation that the diligent expert investigation now actively prosecuted will presently yield us such knowledge of the nature of its germ and its nativity, as will enable us to strangle it in the place of its birth The pregnant idea of dealing with germ diseases, that have a localized origin, at the point of their generation was under consideration by the Pan-American Medical Congress at its first session in Washington in September, and it is just such great orgaizations as that, composed of men with enlightened minds, and courageous natures, that will work out the problems of sanitary science and art for the welfare of the world

So far, we have considered prevention of disease on the line of keeping the susceptible people from coming in contact with the germs of disease, but there is another phase of prophylaxis equally important, namely, preparing people artificially, so that although they come in contact with pathogenic germs, they will be able to resist them and suffer no ill, i e , render people immune against contagious disease

The most notable example of this is the fruit of the acute observation of Dr Jenner in discovering, about one hundred years ago, that milkmaids who contracted cowpox were immune from smallpox, and the AMERICAN MEDICAL ASSOCIATION has done itself honor in providing for a Jennerian centennial celebration in May, 1896

The name of Pasteur need but be mentioned to recall the work he has done in the last decade, by virtue of vaccination against rabies in man, and inspired by the genius and success of Pasteur many experimentalists in recent years have essayed to render people immune against cholera, yellow fever, etc , by hypodermic injections of special cultivations of these germs respectively None of these efforts have, however, succeeded

A closely related line of experiments has been most diligently pursued by quite a list of distinguished investigators, in various parts of the world, based upon the theory that it is possible to produce, artificially, such a condition of the human system as exists after an attack of smallpox, scarlet fever, whooping cough or other contagious disease that attacks man but once Assuming that during an attack of such a disease there is something added to the system or subtracted from it, that renders it perpetually immune to that disease, the effort has been made to establish this immunity by making an equivalent change in the system by artificial means, that would not endanger life nor create serious suffering It will be observed that this is but a slight modification of Jennerian vaccination, closely related to Pasteur's arrest of rabic intoxication, and not remote from the idea involved in the original claim for Koch's tuberculin Encouraging progress has been made through experiments on the lower animals, but nothing definite has been accomplished in man

The concept in the premises may be illustrated by reference to what has been done to simplify and extend the Jennerian vaccination Dr Sternberg took the blood serum of a heifer that had had cowpox, and injected it into the system of a heifer that had not had cowpox, and thereby rendered the latter immune from cowpox, as was demonstrated by control experiments

From the result of this experiment, the inference is drawn that if the blood serum of a person who has had smallpox should be injected into the body of a person liable to smallpox, the latter would thereby become as immune against the smallpox as was the person from whom the blood serum was extracted If this inference be well taken, it would seem to justify the broad generalization that we are approaching the time when we may be able to render man immune against all diseases to which he is only once liable To accomplish this, however, even if it be within the limits of human effort, will require further study into the nature and function of ptomaines and leucomaines, toxines and anti-toxines, further allusion to which is not within the purview of this address

BIOLOGIC LAW

I submit this broad and comprehensive proposition, namely in the origin of man and in his development through his savage state, the Stone Age, his cave dwelling career, and up to his present enlightened status, every step has been taken, and every advance has been accomplished, in obedience to a law impressed upon matter in the beginning by the Creator This law is absolute and unvarying, it is the universal law of living things, known as the law of vitality

It has not been given to man to arrest, to abridge, to extend, or even to modify the law of vitality, but man has been given the power to change its application and direct its force even more strongly in a selected direction, and to soften its impulse in other directions, and this man may do to such an extent that the inexpert observer, and the illogical reasoner, may honestly conclude that the old law has been modified, or a new one made, but not so, in every instance when a new law of vitality has been announced, and the search light of scientific modes of collecting related facts and the inductive method of using them has been followed, the most obscure mystery has been found but a heretofore unobserved modification of the application of the normal law of vitality

A recognition of the universal law of vitality, as it applies to man, is the soul of scientific medicine, and the full service of science in medicine is to study the seemingly endless manifestations of vital law under diverse environment, and how its operations may be turned this way or that to ward off illness, to cure disease and to modify human suffering

It is not the duty, nay it is not even the privilege, of the true physician to question why the Creator in the plenitude of His omniscience exercised His omnipotence by impressing matter so that, in the presence of a certain environment, a limited number of the elements of the earth should combine and enter upon a new order of motion, known to us as vital activity in its simplest manifestation, and by orderly appreciation of substance and differentiation of force develop into man, rather than by an exercise of cataclysmic power have created man as he is to-day The *why* of what the Creator has done, is not a legitimate inquiry for the physician—it is the fullness of his mission to study the *how* of what has been accomplished

EVOLUTION AS LEGIBLE AS PRINT

But how do we know that man has attained his present estate, the highest exhibit of creative power, step by step, from primitive protoplasm?

The Creator has written the history of the origin and progress of vitalized matter in the rocks and their débris, in the ocean and its fauna and flora, in the rivers, their eroded channels and their deposited silt, in the wrinkles of the crust of the earth we know as mountains, in the fossils and the bones of extinct animals, in the preserved carbon of our coal beds, and in the living things that to-day inhabit the land, the sea and the air. The history thus written is as legible as print, and as veritable as the history of astronomy, by which we can predicate the eclipses and occultations of the planets for a thousand years, as surely as we know there will be an eclipse of the sun next Monday.

This development, from primary protoplasm to man, has been without arrest or shadow of turning, steady as the movements of the solar system, and to him who will reverently follow its progress there shall come a joy as satisfying and more real than the alleged music of the spheres.

There is no pretense that this harmony is recognized by every one who is called doctor, there are sciolists who practice medicine and practice a good deal of it, who honestly think they see in individual disease under certain circumstances, in localized epidemics and in the great waves of contagious disease that periodically enwrap the world, a wide departure from the law of human existence, as predicated by a beneficent and loving Creator. But while earthquakes and tornadoes, floods at one time and drouths at another, waste the products of the husbandman's labor and rob the people of proper sustenance and we acknowledge the Creator as the giver of the law that brings seedtime and harvest, governs the movements of the earth, and regulates all meteorological changes, we need not waste time to discuss the point with the pseudo-scientist, but turn him over to the logic of the poet who declares

"All nature is but art, unknown to thee,
All chance, direction, which thou canst not see,
All discord, harmony, not understood,
All partial evil, universal good."

CELL PLACE AND POWER

As already intimated, the immediate foundation of all living things is protoplasm, and I may now add that the cell is the primary form of organic life, and is properly recognized as the unit of vitality.

A single cell was the earliest form of organized matter and it possessed the attributes of selecting food, digesting and assimilating it, developing itself and propagating its kind. These are substantially all the attributes exercised by the highest organizations, albeit the wide difference in the manner and extent of the manifestations of these attributes sometimes requires the acumen of the trained scientist to recognize the major as nothing more than an amplification and differentiation of the minor manifestations. Present knowledge authorizes the declaration that all living things are single cells, or an aggregation of cells, with the products of cell metabolism or catabolism.

The history of vitality already recited, teaches that the first cell was a vegetal organism, complete in itself, and an essential condition precedent to the next step in advance, i. e., an organism of two cells, and this the progenitor of all subsequent organisms of more and more cells, presenting every conceivable form, glowing with every prismatic color and all possible combinations thereof, luxuriant in leaf, in flower and in fruit beyond the highest soaring of the human imagination, and to a size culminating in the sequoia gigantea, the great redwood tree of the snowy Sierras of California all cells, the simplest a single microscopic cell, the largest but a countless aggregation of cells.

It is worthy the attention of the student of scientific medicine, that all this extensive, varied and imposing development of vegetation is accomplished without the slightest hint of a nervous tissue.

The primal vegetal cell had made but limited advance when the environment, changing the application of vital force, produced a new feature in the cell organization that constituted the initial link in the great chain of the animal kingdom, quite as extensive, fully as variegated and more wonderful than the vegetal kingdom. The first animal was the similar of the first vegetable, in being a single cell, and the order of the development of the higher animal from a protozoa was identical with the development of the higher vegetation from the protophyte, and this fact is the clinching testimony that the Creator has but one way of building living things, of low or of high degree, and that is through the agency of the cell, the unit of vitalized matter.

Accordingly, we find that the present man perpetuates his species through a cell, the counterpart of the protozoa in which he originated. But in this sense man is a compound being, consisting of male and female, and for perpetuating the human race neither has any virtue without the other. The female in our climatic and other surroundings prepares, secretes, say 400 germ cells during the thirty years of her menstrual functioning, but these cells have no possibility of reproduction without encountering the sperm cells of the male who, in the sixty years of his virile power secretes millions of them, all waste material, except the few that meet the germ cells of the female in the interior of her organs of generation when, in such an event, there is not a simple embrace or union of the two, but an actual conjugation of them, each sacrificing its own individuality to constitute a new cell, having in it the potentiality of a human being.

The conjugated cell receives no additional powers or attributes, the act of conjugation completes all that is necessary to reproduce the likeness of its parents, except nutrition, and this the mother's womb furnishes and contributes nothing else. The conjugated cell at once starts on its career of development and in nine months has traversed substantially all the stages the protozoa passed through in the eons it occupied in developing into man. The story of cell place and power would have no pertinence to the service I have been called to on this occasion, if it were not that every pathological condition that besets the human organization is nothing less nor more than a disturbance of the normal activity of a few, or many of the cells of which it is composed, and when this pathological activity proceeds no further than to create error of function, the whole service of the medical attendant is to remove the cause or render the tissues insensible to its presence, and where the disturbing cause becomes a destructive agent, producing molecular death of a part, the sole reliance of medical science and art is to cultivate cell growth to fill up the void and reestablish the continuity of the tissues. The full recognition, by the medical fraternity, of the rôle of the cell in human economy will be an event to be marked by a white stone. Upon such recognition the future of medicine depends for rapid progress and true results.

MIND INFLUENCE

I may be doing my professional confreres an injustice by entertaining the thought, but I have a loose conviction that the influence of the mind over the physiology, the pathology, and the therapeutics of the body is less thoroughly understood, more inadequately appreciated and consequently more mischievously neglected than any other department of the healing art

The imagination will not only convince a man that he is ill when nothing is wrong but his imagination itself, but it will frequently magnify a slight ailment into a fancied fatal distemper, and a physician who does not discern these relations, or discerning treats them as a bagatelle, falls short of the obligations of his calling and fails in duty to his patients Much of the shortcoming in this department is probably due to the absence of a clear, concise and satisfactory definition of mind and of its relations to and association with, the nervous organization But the lack of exact knowledge on these points need not and should not prevent us from recognizing what is conspicuously plain to all who choose to observe and appreciate the constant phenomena of human life, namely, that the measure of the sanitary condition of every individual is the sum of his physical and psychical activities No man is well who thinks he is ill, and per contra, a man may have serious disorder of his physical organization and yet imagine his health perfect The laconic definition of a well man is "a sound mind in a sound body "

Beyond all peradventure, there are a considerable number of disorders in a limited class of people that can be relieved by so-called Christian science A disordered mind is as much a pathological verity as an inflamed lung A patient who believes he has a definite organic disease that he does not have is, nevertheless, out of health, but the disorder is in his mind not in his flesh, and will be restored as quickly, perhaps more quickly, by a qualified faith healer than by the most accomplished disciple of Esculapius Even where disease has been diagnosed and can be successfully managed only by medicaments, it must have been within the experience of every practitioner of even a few years' service, that a large percentage of the ailing will progress more satisfactorily if the patient has full faith in all that is said to, and done for him If to these patent facts we join the pregnant one, that many persons with diseases even acute ones of alarming presence, will be restored to health by natural processes without medicines, the assertion that persons claiming to be dangerously ill and recovering under the management of 'so called spiritual healing does not authorize the conclusion that the patient did not have threatening disease, nor does such recovery warrant the claim that the treatment was influential in the cure

All physicians are familiar with the nature and severity of the grosser developments of hysteria, but it should be fully recognized that from these typical cases there is a diminishing series to a vanishing point, and that the milder members of this series, while frequently independent, are perhaps more frequently complications of disorders not belonging to the neuroses, but which not only embarrass the practitioner in diagnosis and therapeutics, but induce him to administer perturbating medicaments where patience and placebos were the true remedies Indeed, it is just here where the professional sins of both omission and commission in daily routine practice reach their most abundant mischievous results

Much of the perplexity of comprehending the influence of the mind on the body, in all its vital operations is remedied, where one has acquired his knowledge of the nervous system through study of its physiology with a minimum of attention to its anatomy, and in this study made no attempt to unravel the complicated service of the encephalic ganglia in man until he has reached that highest evolution of the nervous system after inaugurating his study by a comprehension of its shadowy appearance in the protozoa, and following up its development, step by step, through all the links of the chain of changes from the protozoa to man By this line of investigation, much of the obscurity in the functioning of that part of the nervous organization peculiar to man, and especially of the gray matter of the cortex of the cerebral hemispheres which is the chief organ of the mind, is removed

To one thus equipped, the mystery of Christian science, of faith cures, of spiritualism as a medicine, of witchcraft, of mesmerism, of hypnotism and similars, is dispersed and leaves a mind thus clarified to walk the way of scientific medicine, cleared of the nebulous mists that hinder and of the clouds of doubt that confuse

To accept the vagaries of the professors of these occult arts is only to a degree more unwise than to deny or deride all foundation for them Both science and clinical experience, as well as common observation, confirm the existence of a varying psychic state under diverse names including spiritualism, mesmerism and hypnotism It is the reasonable duty of the scientific physician to winnow the two grains of truth from the two measures of nonsense in which honest ignorance and unscrupulous chicanery has enveloped it In this direction, Mr Ernest Hart has done a most excellent service, by investigating the hypnotic teachings illustrated by marvelous frauds in the great Paris Hospital of La Charité, conducted by Dr Luys of world-wide notoriety Within the current year, Mr Hart has presented in detail his method of investigation and its results, published in a thin volume in London, which has been reproduced in this country by the Appleton's of New York To persons who have only a hazy view of hypnotism, and to others who see it in full light but enjoy a cutting scientific exposure, without malice, of a charlatan who has long posed before the world as an exalted scientist, this little book will be a boon

I have covered my points, consuming my allotted time If I have seemed dogmatic the occasion offered opportunity for nothing more

Resumé —If I have been successful in an effort to make myself intelligible you will understand me to hold

1 That there is rapid progress in preventive medicine, that its present advanced status is highly appreciated, and that we may confidently look for yet brighter results in the near future

2 That our present concept of the complicated organization of the human body is based on the theory that the Creator, in the beginning, endowed vitalized matter with a perpetual law by virtue of which man has been developed, step by step, from primitive protoplasm

3 That there is no longer dubiety in the proposi-

tion that the cell is the unit of vital activity, and that all living things are a single cell or an aggregation of cells and cell products

4 That the influence of mind on vital activities, normal and abnormal, is not recognized as it should be, and that there is a line of study that would if properly pursued, dissolve the agnosticism that has in the past embarrassed a knowledge of the reciprocal relations of matter and mind

Doubtless you are ready, from sentiments herein expressed, to class me as an optimist, but I hope I am a reasonable optimist, holding my position consonant with demonstrated facts, an optimism that comes of attention to the progress of science, confirmed and brightened by my intercourse with my confreres under the best possible circumstances, namely, meeting them in great, enlightened and cheering associations like this

METHODS OF TEACHING CLINICAL MEDICINE

Read before a Pedagogic Section of the Pan American Medical Congress, Washington, September, 1893

BY FREDERICK C SHATTUCK, M D
JACKSON PROFESSOR CLINICAL MEDICINE IN HARVARD UNIVERSITY, ETC
BOSTON

Whether there is anything perfect in this world, I do not know That it is possible to improve the teaching of clinical medicine in this country, at least, I feel quite sure at the same time, also, I recognize the advance which is certainly making, and am convinced that this will continue We believe that the best is none too good for us, and propose to have it To hasten and secure progress in the future it is well to understand and consider the past, and the lines along which evolution has worked to bring us where we are We must also bear in mind the local conditions, with the advantages and disadvantages which they entail The problems are, to make the best of what we have got, to get more, and gradually to surmount the bars to progress, whether these are accidental or inherent in the spirit and institutions of the country

It is easy enough to see the advantages of governmental control of the higher education, as exemplified in European countries Professors are government officers hospitals and laboratories are built and maintained by the State All the parts which go to make a complete medical school should therefore work together like the parts of a machine, well oiled by National appropriations But it is not likely that we shall see any general adoption of this system, or anything similar to it in this country, even if it were desirable that we should

While the town or municipality properly insists on and provides for primary education with us, intelligent private liberality must in the future, as it has done in the past, provide in the main for the endowment of advanced and professional education Laboratories of all kinds, including hospitals, cost so much to build and maintain that no medical school can pay its bills from the tuition fees of its students, even if a self-denying and devoted faculty is willing to forego all direct pecuniary returns It is to the honor of this country and of American public spirit that there are good medical schools, the teachers in which have, from the start, adopted this unselfish plan of devoting every cent of surplus to improving the facilities for teaching

Without endowment it is impossible to provide all that is needed Endowments will not flow towards proprietary schools, which are exposed to more temptation than is desirable towards a lowering or half enforcement of standards They will, however, flow to schools which are really parts of universities, and I believe that we can rely absolutely on the intelligent private liberality of our citizens to provide all that is required But we must make our wants known, and indicate the means by which they can be best supplied Everything comes to him who waits

Allow me now rapidly to touch on the beginnings of medical education in this country, and the manner of its growth

Roughly speaking, a century ago we became an independent people, full of virile energy, and with ample opportunities for its exercise in the development of a vast and rich territory During the Colonial days we looked to the parent country for professional education, as well as for many other things With independence came an increased stimulus to provide more fully for ourselves The Medical School of the University of Pennsylvania had been already started That of Harvard began in 1783 with three professors Other schools gradually followed Medical education before this was obtained entirely from a preceptor, whose students compounded his pills and draughts, read such books as he had, drove about with him on his rounds, and assisted him in many ways, even to the care of his horse perhaps For many years after the establishment of medical schools, clinical teaching remained in the hands of the preceptor But it marked a distinct advance, when opportunities were offered to enlarge the minds of students by coming to a city and hearing the leading facts and theories of medicine set forth by broad men of large and varied experience Clinical teaching was then wholly derived from the private practice of the preceptor, systematic and didactic teaching formed the lecture course of the medical school The number of men who could get their professional education in whole or in part, in European capitals was very small

The medical school was a private institution, responsible to no one in theory, though the board of trustees of eminent laymen chosen to add respectability and eclat to the enterprise, sometimes proved to be masters where they were intended to be servants Or affiliation was sought with some existing university But this connection was generally a loose one, the university practically doing nothing but confer the degrees on those recommended by the medical faculty The schools were essentially proprietary This was the case at Harvard until twenty years ago, when the union became real and organic It is only two years since the College of Physicians and Surgeons of New York, became really a part of Columbia College

Medical schools antedated hospitals The largest cities in the country one hundred years ago were small, the population was practically native, and there were very few poor requiring hospital treatment The development of hospitals in this country, practically, is included within fifty years, when the stream of immigration began to change from a brook to a river Medical schools being essentially proprietary, and being active only a few months in the year, hospitals were a separate foundation and grew up under separate management, a misfortune which perhaps could not have been avoided under the circumstances, but a great misfortune nevertheless, and one which still weighs heavily on the great majority of the schools of the country Medical schools were founded by physicians, hospitals by benevolent laymen, always, it is true, with the active cooperation, and oftentimes distinctly as a result, of professional influence But the two were under separate management, and it was natural enough that laymen should consider the introduction of students in a hospital as a drawback, rather than a help to the patients, and that they should be unwilling to hand over the hospitals to a proprietary medical school, which could give no guarantee of permanency or of reasonable freedom from selfish action

Under this mode of hospital foundation, the service was divided up among the leading or most active medical men of the town or city If a teacher had a service of three or four months—the duration of an old-fashioned lecture term—he was satisfied Indeed, he, in common with the non-teachers, preferred a short term, as allowing more time for private practice, the emoluments of which he required as those of his teaching position were indirect and uncertain Thus arose a second great drawback to clinical teaching,—a drawback which is the more felt now that the older schools undertake to furnish entirely, or in much larger measure than formerly, the bedside instruction of the old preceptor

In a word, then, the two chief difficulties with which we have to contend in this country in developing firstrate and sufficient clinical teaching, are, the lack of complete union between medical schools and hospitals, and the system of broken hospital service Another and incidental disadvantage is the impossibility of calling clinical teachers from other places In the purely scientific branches, it is merely a matter of providing a salary, but the school which does not own its hospital can not provide the clinical teacher with a hospital service

It will, of course, be understood that I am speaking broadly There are schools in this country which own their own hospitals and can regulate the terms of service therein But I think I am safe in stating that, with the possible exception of McGill University in Montreal, there is not a single one of the leading schools which absolutely controls sufficient clinical material for the methods of clinical teaching which prevail at present, much less for such methods as we should aim to follow in the future The Johns Hopkins will start with a clean slate, on a proper system, and with every facility for the best and most thorough clinical instruction All friends of medical education must watch its course with the greatest interest Its success must stimulate other schools to make more of the advantages which they possess, and must strengthen their hands in the struggle to secure those which they lack

It must be added that in spite of the disadvantages under which we labor in this country, as a whole, the practical working of things is not so bad as might be expected The laymen who manage private and endowed hospitals are enlightened men, as a rule, and are realizing more and more that the interests of their sick charges, as well as the reputation of their hospitals, are subserved by the instruction which is carried on within their walls And I can see a current setting toward a diminution in the size of the staff and a consequent lengthening of the term of service

There is much more that might be said—and doubtless better said—on this broad theme of the relation of medical schools to universities and hospitals It is a fundamental question If we can secure and control further opportunities for clinical teaching, the subsequent details present no special difficulty

To a brief consideration of these details I must now pass on I do not know where and when the first Chair of Clinical Medicine, independent of that of Theory and Practice, was established in this country, and this little paper is written far from any medical center or books It is rather less than forty years since the Chair was founded at Harvard, and my father was its first occupant Since this time the increase in the amount of clinical instruction has been, on the whole, steadily progressive In the twenty-five years which have passed since the writer began to study medicine, the number of exercises per week in clinical medicine have been multiplied several times, and the four years' course the success of which must depend largely on clinical opportunities of all kinds, is bringing still further increase in amount with, it is hoped, some corresponding improvement in method

The clinical lecture to large classes in the amphitheater, which marked the commencement of instruction in clinical medicine, maintains and always will maintain a place Much instruction can be imparted in this way, with economy of time to the student and of teaching force to the school However careful and ample the drill of the individual student may be made, I believe that the clinical lecture will survive During a year a wide range of disease, as well as much of the variation of individual diseases, can be illustrated by patients drawn both from the wards and from the out-patient department The student is thus shown methods of diagnosis and treatment, his attention is called to the changes in structure and function which disease works in the living body, and the particular case can be made to illustrate general principles But the work is done for the student, and must be done for him, in the main The limits of an hour, and the enlistment of the sustained interest of the class, as a whole, do not permit the drill of one or two individuals whose profit is largely at the expense of the main body In many of the schools of this country clinical lectures to a full class are given in sufficient number and of high quality

What, practically, all the schools need most is the clinical drill of the individual student and a close contact between student and patient This implies a wealth of clinical material and a considerable number of instructors among whom the class can be subdivided, so that each can have the precious opportunity of observing and finding out for himself The ward visit is a valuable means of instruction in rendering it possible to see and follow out diseases and cases of disease which can not well be transported to the amphitheater But it is hard to make a ward visit profitable to more than a dozen students at once, and the management of an independent hospital is apt to look askance at a method which tends to increase and complicate the work in the ward in ways which it is not necessary to elaborate

There is one feature in particular of the English system of clinical teaching, which has always seemed to the writer most admirable Each student must serve a fixed number of months in the ward as clinical clerk, with certain cases for the care of which he is responsible under supervision, and with all the details and course of which he necessarily becomes familiar It is thus impossible for him to enter practice without any practical experience whatever, and, what is more important, he is forced to exercise his powers of observation for himself The identity of school and hospital make this system easily possible And yet it has not been attempted in European schools to any extent, as far as I know Anatomy can not be learned without dissection, chemistry, without laboratory work Nor can clinical medicine be learned in the best way without work in a hospital ward and out-patient room

It is possible that much use could be made of the sick poor at their homes under the charge of dispensary physicians, though there are practical difficulties in the way I believe that along this line lies the first present necessity and opportunity for development The recognition of the necessity is the first step toward the provision and utilization of the means

There should, again, be primary as well as advanced clinical instruction In the new schedule of studies under the four years' course now in operation in the Harvard school, this principle receives full recognition The course in the second year is entirely separate from that in the third, that in the third will be more or less independent of that in the fourth year Each student will have in his second year four hours a week, partly clinical lectures and demonstrations of semeiology and diagnostic methods, partly drill in small divisions in physical diagnosis, partly ward visits in the hospital The general scheme for the third year is to provide more advanced instruction in the wards and amphitheater, including therapeutics, as illustrated by the case or cases in hand In the fourth year it will be the aim to make the work as practical as possible, and give the student opportunities to apply and fix the knowledge which he has already gained, at the same time that he increases his stock by more intimate contact with disease

Many years ago my father introduced an exercise in clinical medicine which has become popular and been adopted by other departments in the Harvard school, to which it is still, as far as I know, peculiar It is called the clinical conference Each student in his final year is provided with a selected case, usually in a hospital ward, though sometimes in a dispensary district He is expected to visit and follow up this patient, and write a practical paper on the diagnosis, prognosis and treatment A month or six weeks is allowed for the preparation of the paper, which is then handed in and which counts a fraction toward the examination for the degree From these papers a selection is made, according to character and subject, and every week one is read by its author before the class and a number of instructors in the department The reader is then subjected to criticism and question by his fellow students and teachers On the preparation of these cases much pains is bestowed, and I think there can be no question that the exercise is a useful one It is a matter of honor that the work on the case should be really that of the student himself Under the four years' course, instead of one, I hope that each student may receive a number of cases to look up in this way

I believe that the future is bright with promise The progress in a century has been enormous At first we depended almost wholly on Europe or Great Britain for a firstrate medical education Then students crossed the water for clinical advantages in hospitals, as these were non-existent or small in this country Then a prime inducement was the chance for laboratory work,—physiological, pathological, histological, biological Just as our hospitals have become second to none, so will our scientific laboratories It will always be enlarging to the mind to visit foreign schools and study their methods But it is no longer necessary for the attainment of an excellent equipment, alike in practical and scientific medicine We should bear in mind the fact that we have many possessors of large fortunes, who will quickly see that in no way can they so usefully and with so much credit to themselves dispose of their surplus, as by promoting medical education within, as well as outside of hospitals But the matter must be laid before them, as it can not be expected that they should be familiar with the requirements of clinical teaching Who is so fit to explain the matter, and who can exert more influence, than the family physician? Even if a teacher himself, he can not be considered a specially interested party if he is an officer of a university, which goes on forever, and the management of which can be depended on to administer funds intrusted to it, strictly within the purposes and wishes of the donor

RARE FORMS OF GOUT AND RHEUMATISM

Read before the New York State Medical Association, Oct 11 1893,

BY SIR JAMES GRANT, M D , K C M G

OTTAWA, CANADA

Mr President and Gentlemen —This I consider "a red letter day" in my professional life's work, and more particularly from the very fact of having received so generous an invitation, through the Secretary of your Association, to read a paper on this auspicious occasion We Canadians, as a whole, delight in noting the advance of our American neighbors, in almost every line of thought in medical and surgical science The assembled wisdom of this Association from the great State of New York, almost a kingdom in itself, is only an index to the intellectual power to day at work in almost every State of your prosperous republic How gratifying it must be to con over such names as Rush, Mott, McDowell Sims, Gross, Pancoast, Flint, Sayre, Thomas, Emmett, DaCosta, Bowditch, Goodell, Pepper, Weir Mitchell, Bull, McBurney and a host of others equally great, but too numerous to mention, who by their skill and ability have added luster to the name of America

To day I propose offering some observations on rare forms of gout and rheumatism, conditions not by any means frequent as to their occurrence

PNEUMONIC GOUT

The following brief notes are of a pneumonic form of gout, associated with slight hepatic complication
